

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. 1883

1

would be making a very wide departure alike from the laws of clinical induction and common sense. We have to deal with idiosyncrasy, and must apply our knowledge under the limitations of its laws. It must be remembered, however, as I have already asserted, that idiosyncrasy by no means declines to enter into partnership with other causes of functional disturbance more easy to be understood. The varying state of the patient's health at different periods of age, and varying habits as regards diet at different times, may conceal or bring into unusual prominence an idiosyncrasy which is a permanent condition. In many patients susceptibility to the influence of tea is much increased by taking certain wines, notably champagne, and is diminished by the malt liquors and the red wines. As a rough rule, all idiosyncrasies become aggravated when the tone of the system is low, and many of them pass into almost absolute abeyance under conditions of unusual vigour and health. Idiosyncrasy in respect to tobacco displays itself in two forms, and one of them is of unusual interest, since it exemplifies a class of idiosyncrasies which are very apt to be misunderstood. I refer to those in which the individual susceptibility is not displayed immediately on the incidence of the cooking influence, but waits, it may be, for a long time, and until possibly other conditional causes come to its assistance. A little thought will probably supply most of us with examples of this class of idiosyncrasies, and they are very important in practice. A man who has drunk tea all his life, and largely, may rather suddenly find that it is almost poisonous to him, and may then recollect that one or more of his relations have never from childhood been able to take it. It is the same with egg, fish, and certain kinds of wine, and so also with various drugs, and in all these instances it is, I believe, quite possible that the display of the idiosyncratic susceptibility may be only temporary. In some instances we may discover in some change in the mode of life or habits of diet, or in advancing age, and possibly some visceral degeneration, an explanation of the newly-discovered peculiarity, but in other cases nothing can be found. Tobacco, I think, stands curiously alone amongst the articles in human use in that it almost invariably in the first instance acts as a powerful poison, and that tolerance can be acquired quickly and certainly by almost every one. There are, however, great differences in the degree of susceptibility, and in the ease with which habituation is obtained. Many never do obtain it, and although this in most cases may be merely the result of want of perseverance, there are a certain number in which it would appear that the primary idiosyncrasy is insuperable. Many persons who have acquired tolerance of one kind remain susceptible to others, and after having been habitual smokers for years, may be made very ill by inadvertently using an unaccustomed kind. Many smokers, I believe, recognise periods during which the pipe disagrees with them, and they are obliged for a time to abandon it, and very curious symptoms, such as absolute suspension of the sexual appetite, &c., are sometimes with confidence alleged as consequences of its excessive use. But the cases which are of most interest in connection with our present subject are those in which without any undue excess and in persons who have been for long thoroughly habituated, tobacco suddenly begins to act as a poison without causing any distaste or any conspicuous derangement. These patients are often quite unaware of what it is which is hurting them. They lose appetite and become nervous, and amongst the most conspicuous symptoms is a very marked failure of sight. This failure differs from all other forms of amaurosis or amblyopia. It always affects simultaneously and equally both eyes; it begins very insidiously, and having no other symptoms in diminution in acuity of vision, is often scarcely recognised by its subject until at the end of six weeks or two months he finds that he can only read the very largest types. When at its height the optic disc is usually red and a little hazy, and at a later stage it becomes decidedly pale. If the patient will for a while leave off smoking, he will

regain his sight almost to a certainty, but, however perfect may be his apparent recovery, the disc is almost always left pale. He may resume the habit after a while without much risk of relapse if he keeps to strict moderation, and in some cases recovery takes place, although the abstinence never has been complete.

Such are some of the principal facts respecting tobacco amaurosis. I have felt justified in stating them in this positive manner because I published in a series of reports some years ago in the *Ophthalmic Journal* and the "*Medico-Chirurgical Society's Transactions*" very full details respecting them. That the symptoms in question are really due to tobacco I cannot feel the slightest doubt. I have seen no cases quite parallel to them either in women or in non-smoking men. If in these two classes of patients similar symptoms should be presented, which is very rare, I believe that they always progress without interruptions to almost total blindness. Tobacco amaurosis rarely happens to novices in smoking, and rarely except to those who are liberal in the indulgence. Half an ounce of shag per day has been the usual allowance in the cases which I have collected. In support of my interpretation of the facts I may briefly advert to the history of our knowledge of them. Long before the ophthalmoscope diagnosis was made out, Dr. Mackenzie, of Glasgow, and several French observers, had recognised the malady, and alluding to the difficulty met with in persuading its subjects to abandon the habit, Dr. Mackenzie had used the expression, "There are many who would rather smoke than see." Mr. Wordsworth, at Moorfields, was, I believe, one of the first who studied the ophthalmoscope diagnosis, and he held that the conditions displayed by the disc were pathognomonic. It was to his teaching that I was chiefly indebted for my interest in the subject. I must hasten to the narration of certain facts which show that this disease is really a matter of idiosyncrasy, and that we ought, by recognising the fact, to explain the circumstance that such a very small proportion of smokers ever suffer from it. This immunity of the greater number and the picking out of one here and one there has been a great stumbling-block to many in the way of accepting this doctrine. I cannot think that it ought to have been so, if due allowance be made for the influence of idiosyncrasy. The facts to which I first alluded as supporting the belief that this influence is really at work are the following:—Not very unfrequently the subject of tobacco amaurosis is one who was well aware of his susceptibility, who had experienced unusual difficulty in learning to smoke, and who had never been able to change with impunity from one kind of tobacco to another. Some years ago a young man came under my care who was a smoker, and who had smoker's amaurosis. Subsequently his mother, who did not smoke, came to me for an almost similar state of things, and I then learned that a nephew of hers, a smoker, had suffered just like his cousin, and had been under the care of my colleague Mr. Hulke. I applied to Mr. Hulke for his diagnosis, and he kindly sent me a copy of his notes, showing that he had considered it a tobacco case. Here, then, we have three near relations presenting the same form of disease. In the woman, who did not smoke, the disease did not show itself until twenty years later in life than in the two young men who did, and in them, on abstinence, the disease was arrested, whilst in her it increased. Can we doubt that we have here an instance of family proclivity? I have yet to mention a stronger case in proof that special susceptibility may exist in a family—a hard-worked Welsh clergyman, who had been accustomed to irregular meals, and had consumed in large quantities a cheap, strong tobacco. He became nervous, and almost blind, and he recovered on giving up smoking. He told me subsequently that two of his brothers, farmers, had experienced precisely similar symptoms, and apparently in connection with the same cause. I did not see either of them, but I believe both were, like himself, almost wholly cured by abstinence. These two groups of cases, in each of which more than one member of the same

family suffered from the same cause bear to my mind very strong evidence in favour of the opinion that it is under the laws of idiosyncrasy that we must seek the explanation of chronic tobacco-poisoning. It occurs to those in whom the nervous system, possibly the nervous tissue, has susceptibilities which are not shared alike by other members of the community. I have alluded to the fact that this susceptibility is not usually simple or immediate, as in the case of arsenic; it is almost always in those who have been long accustomed to smoking that these nerve phenomena occur, and they are probably indicative of a state approaching to saturation. If it be asked what are the other contributory causes which assist in producing the outbreak, I should be inclined to suggest that very varied influences which reduce tone may help over-work and anxiety, may assist, and so probably may the sudden loss of outdoor exercise. I do not think that the use of stimulants is often a contributory cause, at any rate, not unless to such excess as to interfere with appetite for food. Many facts which have come under my notice suggest that total abstainers from alcoholic beverages are, if they smoke freely, in much more danger of chronic tobacco-poisoning than those who drink them.

Respecting idiosyncrasies as regards arsenic, I have to remark that they are not nearly so marked nor so common as those respecting some other drugs. I have met with exceedingly few cases in which small doses disagreed. It is very exceptional indeed that a patient complains of inconvenience at the outset of a course. Usually, symptoms occur after the drug has been to some extent pushed, and they for the most part necessitate its discontinuance or reduction. I am alluding now to the well-known symptoms of conjunctival irritation pain in the stomach and bowels. Respecting these, I think tolerance is never obtained, and if once they have occurred they are prone to occur again if the same doses are given. In English practice, individual susceptibility to arsenic does not seem to vary much. Most persons, as I have said, can take it, and very few can take more than a certain dose. I have never myself seen a case in which it could be pushed beyond a certain point with definite disagreement. The most remarkable fact in reference to idiosyncrasy is its occasional production of the form of neuritis which we know as herpes zoster. It is now more than ten years since I published a series of cases illustrating the occurrence of herpes zoster in patients who were taking arsenic, and since then I have seen so many other examples of it that I cannot entertain the slightest doubt as to the direct connection between the two. The herpes eruption may occur in the forehead, face, or trunk, and it is wholly indistinguishable from herpes in these regions when not due to arsenic. It seems the same cause that disappears after its usual duration, whether the arsenic be continued or not. The patient does not, as a rule, show any constitutional symptoms of arsenic intolerance, and it is almost invariably the case that he has taken the drug for some weeks before the symptom appears. The advent may now and then be delayed until a week or ten days after the course has been suspended. A precisely similar interval is sometimes seen in cases of sympathetic ophthalmitis, in which affection probably, also, a form of neuritis—the inflammation of the second eye—may begin to develop a week or ten days after the entire removal, by excision, of its cause. These facts would suggest that the neuritis is in each instance slow in its stages, and that, having been once initiated, its local processes cannot be stopped. The number of those who show arsenical herpes is very small in proportion to those who escape, and, if it is to occur at all, I think it always happens during a first course. I have never seen it in a patient who had been accustomed to the drug for a long time. Thus, its occurrence must certainly rank as the result of an idiosyncrasy; and this suggestion opens the way for the further one—that we ought, perhaps, always to regard herpes zoster as, in the main, an indication of personal peculiarity. It certainly does not appear that all persons are equally liable to it, since it happens to but

very few, and is never associated with any special form of ill-health. Excepting the single fact, just alluded to, of its occasional production by arsenic, we know of no causes which can evoke it. I have seen arsenic produce herpes in two different regions at the same time, but I do not remember to have ever witnessed a second attack in the same individual. In reference to this, however, it is but fair to add that I have usually carefully avoided this drug after an attack of shingles, since the latter is very often a very serious trouble. A few—a very few—persons are liable to the occurrence of an eruption of herpetic vesicles over and over again in the same part of the skin, and, as is well known, examples of recurring herpes on mucous membrane are very common, as, for instance, on the lips and genitals. Sometimes recurrences take place once a month, or even oftener, the eruptions always passing through the usual stages, and undergoing a speedy and spontaneous cure. There is never any peculiarity of health to be made out in explanation of these cases, and they must, I suppose, rank as idiosyncrasies. Homœopaths are welcome to make what use they can of the fact that arsenic will often cure these cases and prevent the recurrence. I have repeatedly seen herpes of this kind remain in abeyance for many months whilst the patient was taking arsenic, and show itself again when the drug was suspended. I have seen one case which to some extent offers an exception to some of the statements which I have just made, inasmuch as the patient was liable repeatedly to an eruption from arsenic. The eruption always came soon after beginning the remedy, and he was well accustomed to its use. The patient is a gentleman now near to sixty, who has suffered from psoriasis most of his life, and for whom in early life Sir Benjamin Brodie prescribed arsenic. He has often taken it since, and its usual effect is as stated. On one occasion he took it in order to show me the character of the eruption produced. It had been called eczema, and, although it certainly had the local features of an ecthymatous eczema, yet it occurred, like herpes, unsymmetrically on one arm in large pustules, which disappeared spontaneously after a few days.

SPONTANEOUS GANGRENE OF THE SKIN.

By Professor NEUMANN.

Abstracted and Translated from the *Wien. Med. Zeitung*,
By Dr. J. E. BURTON,
Physician-Accoucheur to the Lying-in-Hospital, Liverpool.

PROFESSOR NEUMANN reported to the Royal Society of Physicians of Vienna at the meeting held on May 12th a case of spontaneous gangrene of the skin. He characterised it as among the rarities in the annals of medicine, if, indeed, it was not unique. Cases of the disease had been published by Nilson, Bjerling, Bruniche, Bull, Dujardin Faure, and particularly Raynaud, Englich, and very recently Weiss, of Prague; but in all these cases prodromal symptoms had been observed, affections of the central nervous symptoms had preceded, and the gangrene had developed gradually within the space of a few days. Prof. Neumann's case, on the other hand, had not its centre of interest in the distribution of the gangrene, but in the acuity of the onset of the affection. The subject of the disease was a girl, 18 years of age, anæmic, with scanty menstruation. She suffered in childhood from scrofula, and several years ago underwent an operation for a cavernous tumour on the sole of the foot.

The present illness, dated from Oct. 15th, 1881. The first gangrenous spots showed themselves in the hollow of the hand, and ranged in size from a grain of linseed to a "silbergroschen," and were seven in number. Hereupon efflorescences, the size of a thaler, made their appearance, on the left sterno-clavicular articulation, then on the manubrium sterni, and on the external curvature of the clavicle, and in this region nine gangrenous patches of almost equal size were visible. Then both

forearms became affected, and upon the external surfaces, in the following order: first came four patches on the left arm, then three on the right, one on the left, two on the right, one on the left, one on the right, and, finally (May 12th), two more, the size of a thaler, below the left patella.

The appearances under which the sloughing took place changed; but a burning sensation lasting from five to ten minutes was always said to be present; the skin over a circumscribed spot became reddened, somewhat elevated, and the temperature was raised. These patches gradually separated from the healthy skin, and it was noted that the skin gradually changed its colour from the circumference to the centre, that the former looked brown, and the latter a dull white. By this time sensation was gone at the periphery, but was retained at the centre for about half-an-hour, to disappear, however, completely as soon as the cutis had become completely changed. During these changes it was observed that a serous fluid was exuded in the neighbourhood, so that from some of the patches, ray-like prolongations shot out, not unlike those seen on the skin of people who have been struck by lightning. The slough was separated in from ten to fourteen days by quickly growing granulations. On two sloughs that had been early removed by scissors, microscopic examination revealed the unchanged panniculus adiposus, as well as the dilated veins of the subcutaneous connective tissue.

Professor Neumann confessed himself unable to state the cause of the disease; he thought that it was plainly something in which the vaso-motor nerves played a part.

Docent Dr. N. Weiss thought Professor Neumann's case was probably one of disease of the peripheral nerves.

Professor Billroth (President) said he had an impression that the sloughs were works of art. The disease might be called a mental one, that drove the girl to practise this deception on the physicians. The diseased parts looked as if they had been touched with caustic potash. The case had not the slightest likeness to those related by Raynaud. There the patients were delicate, anæmic Frenchwomen, who had exceedingly fine blood-vessels, in whom, finally, the circulation ceased at the finger tips, the integument of which first became bluish, and then died. If healing took place, the granulations were pale and flabby, and months elapsed before cicatrization took place. In the case before the meeting, on the contrary, the patient was a thoroughly well-nourished and powerful girl. The spots said to be spontaneously attacked did not correspond either to the course of a nerve or of a blood-vessel; the granulations, after the throwing off of the slough, were splendid, for sloughs caused by caustics, most characteristic. And how could it be explained that behind the very pieces of cutis that had died for want of nourishment the healing process was so vigorous? Unless there was something miraculous about it, and he (Professor Billroth) was no believer in miracles, the case was absolutely inexplicable. On the other hand, it was only too well known what hysterical women will do, to make themselves objects of interest—how they will swallow needles, or stick them in anywhere, or do something or other to themselves that causes great pain. The first thing to do was to ascertain whether any deception on the part of the girl was at the bottom of it.

Professor Neumann energetically opposed the view of the last speaker; he had expressly said that he had observed the case; he had designated the case as unique, and could not believe there was any deception about it—it was a disease.

Professor Billroth could only repeat the words of his teacher Romberg: "Never believe women, even if they seem to be dead." (*Glauben Sie nie den Frauen, auch wenn sie todt zu sein scheinen.*)

It was then agreed to refer the slough to Professor Ludwig for chemical examination.

Clinical Records.

NEWCASTLE-ON-TYNE GENERAL INFIRMARY.

Uræmic Convulsions treated with Pilocarpin.

Under the care of DR. PHILLIPSON.

Reported by JAMES LIMONT, M.B., Senior House-Surgeon.

J. M., æt. 44, labourer in iron works, admitted April 20, complaining of swelling of legs and abdomen with difficulty of breathing, of twelve months' duration.

Mother and brother died of dropsy. No history of scarlet fever or rheumatism, but has been a great drunkard, and has been much exposed to alternate heat and cold while working at the forge. Twelve months ago his urine diminished, swelling appeared round the eyes in the morning, but he had no pain in back or head, nor any sickness. Was treated in this infirmary at that time, and left hospital about the end of the year. He only worked a few weeks when he began to be troubled by pain in back and head, frequent micturition, with diminution of urine and swelling of face and legs.

When admitted was markedly anæmic; great œdema of legs, extending over back and abdominal walls; ascites considerable. Weighs 14 st. 2 lbs., weight in health being 10 st. 2 lbs. Very weak, and unfit for slightest exertion. Digestive system much disturbed; no appetite; constipation. Arterial tension high. Shortness of breath, with effusion into both lungs. Slight pain in back, urine much diminished in quantity, albumen plentiful, casts fatty. Prescribed acetate of ammonia and compound jalap powder, with a vapour bath every evening.

April 25th.—(œdema diminishing, otherwise no change.

26th.—During night patient became unconscious, and had several convulsions. Chloral hydrate and potass bromide (grs. 40 of each) were given *per rectum*; a wet pack was tried, to induce diaphoresis, but without the slightest effect. One-third of a grain of pilocarpin was then injected subcutaneously, and in less than five minutes there was very profuse perspiration, which lasted for several hours. Patient remained unconscious for twenty hours, but there was no return of the fits during that time.

27th.—œdema now greatly decreased; pilocarpin repeated with same result.

30th.—No trace of œdema to be seen.

May 25th.—Still continues free from œdema; anæmia not so marked. Weighs 11 st. 5 lbs.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

DOUBLE FUNGUS ARTHRITIS OF THE KNEES.—M. Marc Sée related before the Société de Chirurgie a case of double fungous arthritis of the knees in a young girl, and which he treated successfully by injections of iodoform. This mode of treatment had already given good results in the hands of several surgeons, and particularly of Mossetig, of Vienna. In the patient of M. Sée there existed luxuriant fungosities in the left knee; no liquid in the joint, and no fistulæ. An intra-articular injection of sixteen drops of a solution of iodoform and ether was made, but the reaction was very prompt and severe. However, at the end of a fortnight a considerable amelioration was observed. Encouraged by this success, M. Sée made another injection into the opposite knee. Compression was continued for a long time, and two months after the injection both knees were considerably diminished in volume, and walking had become possible. M. Despres, commenting on the case, said that injections of iodoform into the articulations were getting very common. He obtained a manifest amelioration in two cases in which he employed them, but the iodoform treatment was to him quite new. He saw and examined the case of M. Sée, and he was able to discover a good amend-

ment, but the cure was not completely effected. He considered that in that case the best thing would be to seek to obtain an ankylosis in a good position. M. Verneuil could not see quite clearly whether, in the case in question, the existence of fungosities was proven. Fungosities were classed under three heads—those depending directly on chronic rheumatism; those which were symptomatic of osseous lesions; and the tubercular follicles of the synovial membranes. This division was important, for when tuberculous follicles were present amputation should be performed, as resection was always followed by a return of the disease. On the contrary, in the case of a rheumatic affection, compression, cauterisations, iodine injections, and others, succeeded very well. As for the fungus depending on disease of the bone, resection succeeds very well. M. Lannelongue could admit but two varieties of fungus—the tubercular and the inflammatory. A Lyons surgeon gave an account of a case in which he had to open the ankle-joint and scrape the fungi of the articular surfaces. The case did well afterwards.

THE DEVELOPMENT OF LAMBS.—At the Société de Biologie M. Regnard showed the development of six lambs under the following conditions:—Three were submitted to the ordinary vegetable régime; the other three were fed with the same, but with the addition of a certain quantity of powdered blood cooked and dried. The first three lost flesh considerably, while the others became so fat that people declared never to have seen such fine lambs of their age. M. Regnard considered that if further experiments confirmed these results, a great economical advantage would result from the employment of blood, of which several hundreds of thousand quarts are lost in the *abattoirs* of Paris weekly. Other experiments would be tried on calves, and the results would be communicated to the Society. M. Bouley asked why this mode of alimentation should not be employed for children deprived of a nurse; whereupon M. Regnard related the case of a child of eighteen months who was attacked with rickets, and in whom this treatment gave excellent results.

CATARH OF THE CERVICAL CANAL OF THE UTERUS.—This disease not only constitutes a chronic affection disagreeable to the patients, but it is very often an absolute cause of sterility. The incessant production of a tenacious stringy mucus forms a sort of plug which holds the uterus in a state of permanent occlusion; hence the sterility. Outside of surgical means applicable to this affection, Dr. Cheron, of the Hôpital St. Lazare, has obtained the best effects from the following treatment:—After having properly cleaned the cavity of the cervix by means of an injection practised by a syringe, he places in the canal a pencil of bread-crumbs, which is steeped at the moment of the application five or six times in a strong solution of tincture of iodine (tincture of iodine, one ounce; iodine, one drachm). The pencil is maintained *in situ* by a plug of cotton, to which a string is attached, in order that the patient may be able to draw it out two or three hours afterwards. This treatment is renewed as often as necessary.

In the *New York Medical Record*, Dr. Steele, of Denver, describing a new remedy for pruritus, says:—"The remedy is sulphate of quinia rubbed up with only sufficient lard to hold it together. The nearer you get the full strength of the quinia, the more efficacious will it prove. Apply freely and thoroughly. It has proved a specific in my hands."

GENERAL MEDICAL COUNCIL.

FIRST DAY, TUESDAY, JUNE 27, 1882.

THE thirty-third session of the General Medical Council commenced on Tuesday, June 27, when the following new members were formally introduced to the President:—Mr. John Marshall, Mr. J. Collins, Dr. Lyons, Dr. T. K. Chambers, and Dr. Patrick Heron Watson.

Dr. Acland then delivered the Presidential Address, to which reference is made in another part of our present issue.

REGISTRATION OF MIDWIVES.

A Bill providing for registration of midwives in England and Wales having been submitted by the Lords of the Privy Council for consideration by the Council,

Dr. QUAIN moved that the draft be referred to a committee to report thereupon.

Dr. LYONS called attention to the fact that the Bill was unendorsed, and he wished to know its source.

The PRESIDENT pointed out that it was forwarded from the Privy Council. A week ago he had received a letter on the subject from the British Medical Association, which letter had been submitted to the Executive Committee. This had been followed by a second letter from the Privy Council office, on the same subject.

The motion of Dr. Quain having been seconded by Dr. Pyle,

Sir WM. GULL suggested that the Council decided that the subject was one for consideration, and that the matter should not be so hastily decided on, especially since the members of the Council were ignorant of the contents of the Bill.

Dr. QUAIN said the proposed committee would tell them what was in the Bill, and enable it to be considered with greater facility.

Mr. SIMON said the usual course would be to refer the Bill to a committee, but urged that the present was not a suitable time for introducing it, especially since the Council's tenure of existence was uncertain. He approved the scheme of the Bill, but deprecated creating the Council in its precarious condition a new educational authority. The Bill might more appropriately follow after amendment of the Medical Act. He thought that some clauses of the Bill would demand careful discussion, especially those making part of the expenses to be incurred payable by the Council.

Mr. MACNAMARA thought the Bill should be referred to a committee. It dealt with a most important subject, and it ought to be considered whether its provisions should not be extended to Ireland and Scotland.

Dr. LYONS remarked that the proposal of the Bill was a very wide one, viz., to tack on to the Council, in some ill-defined way, responsibility for the action of an unlimited number of women. The Council should carefully deliberate the matter, and, before it resolved on any action, free ventilation of the Bill in the press should take place, and opinions on it be obtained from the profession. The Bill really made the Council liable for its successful operation, and its extension to Ireland and Scotland would before long ensue. The Council ought not to commit itself to any definite utterances on it at present. Legislation on the matter must of necessity be deferred; he moved as an amendment that the Bill be taken into consideration at the next meeting of the Council.

Sir WM. GULL proposed a similar resolution, which Dr. Lyons seconded.

Mr. TURNER said the amendment practically called on the Council to abrogate its function. The Council was accustomed to consider all bills referred to it by the Privy Council. Not to do so would be to treat the Privy Council in a cavalier fashion. By referring it to a committee the Medical Council would not pledge itself to any of its provisions.

Dr. WATSON thought it would be a misfortune if the Council failed to take some immediate action on so important a matter as that treated of in the Bill. He supported the motion.

Dr. QUAIN said the question had been postponed from the time when it was included in the Duke of Richmond's Bill, and the urgency of the subject demanded its immediate consideration.

Sir WM. GULL insisted that the consideration of the Bill should not begin in the Council, but should be initiated by the profession generally and by the country. Moreover, the question of expense was one that the Council would be deeply concerned with. The Council should not act too hastily.

On a division, the original motion of Dr. Quain was carried.

Drs. Storrar, Chambers, Banks, Mr. Marshall, Mr. Watson, Dr. Pyle, Dr. Quain, and Mr. Humphry, were elected on the Committee.

DENTAL BUSINESS.

The Dental Committee presented a report on the case of Thomas John Molloy, whose name had been removed from the list of Dental Licentiates of the Faculty of Physicians of Glasgow, and the solicitor to the Council said this qualification should cease to be printed in the Register. A motion to this effect was then carried.

A second case reported on was that of Valdeck Cartwright Mallan, who had been found to have been carrying on practice in his own name at two addresses, and in other names than his own at two other establishments. He expressed willingness to put his own name up at all the places at which he carried on practice, and the Council taking this into consideration, decided, after an hour and three-quarters' private deliberation, that Mr. Mallan should be requested to discontinue his former practices; and on receiving a promise to that effect the matter ended.

SECOND DAY, WEDNESDAY, JUNE 28.

PRELIMINARY EXAMINATIONS.

The Preliminary Examination Committee appointed in 1881 having presented their report, which was received and entered on the minutes,

Dr. HALDANE then proposed, and Dr. STORRAR seconded: "That the *Recommendation* of the Council at present in force in respect of the Natural Science subjects in the Preliminary Examination be not at present changed."

Rev. Dr. HAUGHTON referred to the fact that five corporations had replied to the original minute, two of them expressing the opinion held by himself and the University of Dublin, to the effect that it was not right to insist on every licensing body taking on itself the functions of a university in respect to preliminary education. He approved of the principle of the motion.

Mr. SIMON concurred in the resolution, which was carried.

Dr. STORRAR moved, and Rev. Dr. HAUGHTON seconded: "That a Committee be appointed to consider and report to the Council on the List of Bodies whose Examinations in General Education are at present recognised by the Council."

Dr. Storrar felt that a very large number of examinations were admitted on the list, many of them being highly superfluous. One American university having been recognised by the Council, all other American universities sought the same privilege. The action of the Royal College of Surgeons of England in abandoning its special examination perhaps suggested the advisability of waiting to see how far such a course might be followed by other medical bodies, and that, therefore, consideration of the motion might be deferred.

Rev. Dr. HAUGHTON seconded the motion, and observed that the present was a most opportune moment to raise the question. The Commissioner's report was the most worthless public document ever issued.

Mr. MACNAMARA supported the motion. It was most desirable to clear the list of all but reliable examinations. Many of the colonial examining bodies could only be regarded as doubtful authorities for examination purposes. The Arts examination of the College of Surgeons of Ireland was conducted by men of high attainments. It would, however, be glad to resign its examination.

Mr. COLLINS said the Apothecaries' Society of Ireland was also anxious to give up its preliminary examination.

Mr. TURNER objected to the grounds on which the motion had been supported. The Executive Committee carefully considered the claims of bodies seeking to be placed on the list, so that the list could not be termed "indiscriminate." Except Michigan College and certain continental examinations, all those on the list were connected with England or the colonies. So long as the examining bodies deserved recognition it would not be right to cut them out on account of mere numbers.

Prof. HUMPHRY explained the plan on which the Executive Committee granted applications to be admitted on to the list. The Committee always felt it to be desirable to encourage colonists to complete their professional education in this country by admitting them to registration after passing local preliminary examinations.

Sir WM. GULL suggested that samples of the answers as well as questions set by the examining bodies should be submitted to the Executive Committee.

Dr. STORRAR inquired what hindered the College of Sur-

geons of Ireland and the Apothecaries' Society from giving up their special Arts examination? He would like to know something also about many of the Colonial and American recognised examining bodies. The candidates claiming exemption on account of passing such examinations might be individually required to give information concerning the test they had undergone.

Dr. QUAIN said all the licensing bodies had been requested to communicate any instance of deficient preliminary education in candidates coming before them.

The motion having been put to the Council and passed, Dr. Storrar named a committee consisting of Mr. Teale, Dr. Haughton, Prof. Humphry, Mr. Marshall, Dr. Storrar, Mr. Macnamara, Mr. Turner, and Dr. Fergus.

PERSONATION.

Mr. MACNAMARA moved:

"That it is desirable that this Council should know what provisions, if any, are taken to ensure the impossibility of 'personation' at the examinations of the several bodies, the certificates of which are accepted by them as satisfactory evidence of Preliminary Examination; and that the Executive Committee be requested to inquire into, and report upon, this subject, previous to the next meeting of the General Medical Council."

He said some time ago it came to the knowledge of the Branch Council of Ireland that £200 had been offered to a medical practitioner to personate him at an examination for qualification. At the same time it was ascertained that the candidate who headed a certain preliminary examination of the Royal College of Surgeons was not in Ireland at the time it was held. This, moreover, was not an uncommon practice, and one "grinder" in Dublin kept a well-qualified student to personate candidates at preliminary examinations. This occurred largely at the intermediate examinations. The *modus operandi* was carefully schemed, and the practice aided by the arrangements of the examination. The College of Surgeons of Ireland hesitated to accept an entirely written examination in lieu of its own preliminary examination on account of the facilities for personation offered by the former. The King and Queen's College of Physicians of Ireland stated that 11 of its candidates showed deficient general education, but two were licentiates of the Royal College of Surgeons, and Mr. Macnamara contended these had been personated at the College of Surgeons. Personation, however, could not occur at the final examination of the College of Surgeons of Ireland, because nearly all the candidates were taught and known by the examiners. Personation would not take place at a competitive examination, whether for prizes or for honour.

Rev. Dr. HAUGHTON seconded the motion, and dwelt on the enormity of the offence committed in the offer of a money bribe to a teacher to personate a candidate at an examination in Ireland. Steps had been taken to warn the registrars in Scotland and Ireland to be careful not to register the name of the person who made the offer.

Mr. TEALE said the Visitors of Examinations had been struck by the efficient precautions taken against personation by the various bodies. He thought they should be asked to forward conspicuously deficient papers to the Executive Committee.

Mr. MARSHALL disagreed with Mr. Teale's proposal. The request should be made to the bodies conducting the preliminary examination. It was not incumbent on the Council to question any candidate's knowledge on preliminary subjects when it has received the stamp of an examining board.

The motion was then carried.

REGISTRATION OF MIDWIVES.

Dr. PITMAN read a letter from Dr. J. H. Aveling, requesting the Council to receive a deputation of obstetricians to confer with it on the bill presented on the preceding day.

Prof. TURNER thought the committee appointed to consider the bill should report before the deputation was received.

Prof. HUMPHRY suggested the deputation should be asked to visit this committee.

Rev. Prof. HAUGHTON objected to this course. Action should be taken by the whole Council.

After further discussion, it was resolved that the deputation should be invited to attend on the following day.

VISITATION OF EXAMINATIONS.

Dr. PITMAN moved:

"That a Committee be appointed to consider the *Visitation Reports*, which have been submitted to the Council and

sent to the Licensing Bodies, and the *Remarks* of the Licensing Bodies thereupon, and to draw up a *Report* thereon for the present meeting of the Council."

Mr. TEALE then delivered a lengthy address dealing with the feelings which animated the Visitors in the performance of their duties.

Rev. Dr. HAUGHTON objected to the proposition to relegate the consideration of such an important matter as the report of the Committee to any consideration but that of the whole Council. He proposed as an amendment that the Council should forthwith proceed to discuss the report.

Dr. AQUILLA SMITH seconded Dr. Haughton's amendment. Dr. QUAIN inquired in what order Dr. Haughton proposed to discuss the report.

After some further discussion, it was decided that Mr. Teale should draw up a series of resolutions dealing with the whole report, and submit them to the Council, Dr. Haughton's amendment being accepted.

THIRD DAY, THURSDAY, JUNE 29.

VISITATION OF EXAMINATIONS.

Mr. TEALE discussed the replies of the various bodies to the report of the visitors, and especially that of the Colleges of Physicians and Surgeons of Edinburgh, which, he contended, admitted the conclusions of the Visitors, while apparently raising objections to them on the score of the impracticability of obtaining bodies for examination purposes. He moved: "That it is desirable that every 'primary' or 'first part' examination should include dissections by every candidate."

Sir WM. GULL observed that the difficulty in this connection was admittedly practical. Last year the highest honours at London University were obtained by a woman, who asserted that her excellence was due to careful dissection. The question of numbers to be examined was the important one to be settled.

Dr. LYONS supported the motion. He said the Royal University of Ireland had found no difficulty in dealing with the large numbers of candidates who presented themselves, in respect to practical dissection. He was surprised to hear the objections raised by the Scotch colleges. Cramping in the subject of anatomy was encouraged by omitting practical examination therein. Ample supply of material could be secured at the present time if arrangements were made in view of the necessity.

Dr. PYLE explained that Durham University had been the first to institute dissections as a part of the primary examination.

Mr. MACNAMARA insisted that every primary examination should include dissection from all candidates. "Milk-and-water" resolutions were to be deprecated; they should be comprehensive and exacting on so vital a *desideratum*. Let the Council pronounce a distinct opinion on the necessity of such practical examination. Professor Redfern considered that a scarcity of material was desirable, inasmuch as it would compel deeper and more thorough preparation, since no candidate could be certain of securing an easy or simple dissection. Examination in already dissected parts could not be so thorough as one involving actual dissection. The question of "nervousness" was unworthy of consideration. Irish students, knowing the ordeal before them, were careful dissectors. He moved, as an amendment, that every student at primary examinations be required to dissect.

Mr. SIMON felt the desirability of such a regulation. The excuse for its omission was for the time valid, but could not always be so.

Mr. MARSHALL observed that the majority of the Council of the Royal College of Surgeons of England approved the principle of the resolution, but the practicability of such a proceeding as that involved in the amendment was a question for serious consideration. Only mischief could result from carrying out the more drastic measure at the present time. If really carried out, the plan would starve in the dissecting-room, and thus education would suffer.

Prof. TURNER would oppose the stringent proposal of Mr. Macnamara as being thoroughly impracticable. On the question of severity, also, he urged that sound examination could be conducted without such practical tests. Students ought to be examined on the freshly dissected body. Objects in spirits, dried, &c., were fallacious tests of knowledge. From personal experience, he felt assured that an examiner could form accurate ideas of the extent of candidates' practical knowledge of anatomy by examining them on the dissected parts. In

Scotland the examiner's own personal knowledge of candidates formed an important means of assisting the estimate of each candidate's performance. These circumstances should be considered by the Council.

Prof. HUMPHREY trusted the Council would not pass the utterly impracticable resolution proposed by Mr. Macnamara, but that it would approve of Mr. Teale's milder and more reasonable proposal. He cordially approved the plan of examining candidates in dissection wherever it could be followed; it helped the weaker candidates. At least, two or three hours of such examination would be necessary; it was not, however, he thought, an essential feature of a good anatomical test. At the last examination at Cambridge a larger number of candidates than ever before came up, and the professor of anatomy then, though able to supply bodies on that occasion, felt he could not always be sure of doing so as the numbers grew. He supported Mr. Teale's resolution.

Rev. Dr. HAUGHTON said that for twenty years it was the custom at Dublin University to require students to complete partial dissections, and this, with previous knowledge of each student, enabled the examiner to form a reliable opinion of his attainments. He would support Mr. Teale's resolution.

Dr. BANKS supported the resolution.

Dr. WATSON agreed with Mr. Turner that a practical examination in anatomy was not essential, and supported the resolution of Mr. Teale, but would modify it by adding that "where circumstances permit" the examination should be carried out.

Dr. PETTIGREW supported this amendment.

Sir WM. GULL deprecated the plausible idea that personal knowledge of candidates by teachers should be accepted on the evidence of certificates. The remedy for the existing defects lay in a re-arrangement of examinations.

Mr. SIMON suggested that by inspecting the medical schools examining bodies could form a fair estimate of the work of students in dissection.

Mr. MARSHALL explained the difficulties of re-arranging the system of examinations.

Dr. QUAIN insisted that it was vastly important that students should be examined on the anatomical position of organs, although he by no means thought less of dissection as a means of study.

Mr. MACNAMARA suggested that the tenor of Mr. Teale's resolution were already embodied on the recommendations of the Council.

On a vote being taken, the amendment proposed by Mr. Macnamara was lost, and the original resolution without the addition suggested by Dr. Watson being then put to the Council, was carried.

REGISTRATION OF MIDWIVES.

At 4.15 a deputation consisting of Mr. Ernest Hart, Dr. Playfair, Dr. Aveling, Dr. Holman, &c., was received by the Council, being introduced by Mr. Hart, who explained the object in view. He said that over 10,000 women acted as midwives in this country in 1873. These women assumed these duties of their own free will, and were entirely uncontrolled. The evils arising from the exercise of such functions by scientifically uneducated midwives was pointed out. After sketching the progress of the movement for constructing a register of skilled midwives, and for confining the assumption of the title to those duly qualified by education, and tested by examination, Mr. Hart pointed out that the desire of the promoters of the Bill was that the Medical Council should assist the scheme in view by affording its sanction and assistance in the matter by creating and controlling a central midwifery board.

Drs. Playfair, Aveling, Holman of Reigate, and Sibley having briefly urged the necessity of such a measure.

Mr. MACNAMARA inquired through the President whether the Bill was directed to England only.

Mr. HART explained that Ireland was much better off than England in the matter. If the Bill were successful, and Ireland wished to be included in its operation, it would be willingly admitted.

Prof. TURNER wished to know if the members of the new board would be remunerated for their services.

Mr. HART said this would depend on the surplus remaining after all expenses inseparable from carrying on the scheme had been paid. The whole of such sum would be available if remuneration should be requisite to the members of the board.

Prof. HUMPHRY asked what the feeling of the profession throughout the country was in respect to the bill.

Dr. HOLMAN said that nowhere was it opposed, but that in many places petitions in favour of it had been drawn up.

Rev. Dr. HAUGHTON thought recognition should be given in the Bill to the valuable work done by Irish institutions in respect to midwives. The Bill should admit the rights of holders of diplomas in midwifery from Irish Corporations.

Dr. ACLAND expressed the thanks of the Council for the action of the deputation in communicating their views to the Council, which had long been interested in the subject. The Draft Bill would duly be considered by a committee of the Council specially appointed for the purpose.

VISITATION REPORT.

On the withdrawal of the deputation, Mr. TEALE proceeded to move the second conclusion arrived at by the visitors:—"That, having regard to the great and increasing range of chemical and physiological science, candidates should be appraised beforehand of the limits of examination on these subjects."

Dr. PITMAN pointed out that recommendation 40 of the Council already covered the ground of this resolution.

Sir WM. GULL would have supported the resolution were it necessary to do so. As, however, it was already a recommendation of the Council no more remained to be said of it.

Mr. TEALE modified his resolution to the effect that recommendation 40 should be brought prominently before the notice of examining bodies.

Rev. Dr. HAUGHTON wished to know if the resolution would apply to all corporations, universities as well as others. In that case he would not support the resolution without modification. If carried out it would promote "cramming" and the University of Dublin would never reduce its standard in such a way. The resolution would receive no attention from the University Boards of Examiners.

Dr. AQUILLA SMITH opposed the resolution.

Sir WM. GULL thought that some limits ought to be defined, as suggested by Mr. Teale, and as the University of London had defined in drawing up schemes of examination.

Dr. STORRAR pointed out that the course taken by the London University had been necessitated by experience, but that no limitation in respect of physiology was laid down. He approved Mr. Teale's resolution.

Dr. WATSON thought a distinction should be drawn between chemistry and physiology, that the former ought to be limited, but not the latter, because of its important bearings on medicine.

Dr. STORRAR observed that physiology had become a huge subject, and knowledge of all its branches could not be expected of ordinary candidates for qualifications in medicine and surgery.

The resolution as amended by Mr. Teale was then carried. Prof. Haughton's addition to limit the application of the rule to ordinary licences, and not to University degrees, was withdrawn by consent, on it being shown that the Council's recommendations applied only to minimum qualifications.

FOURTH DAY, FRIDAY, JUNE 30.

THE REPORT OF THE ROYAL COMMISSION.

In answer to Mr. Macnamara, the President said no motion to consider the Commissioners' report had been handed in to him.

VISITATION REPORT.

Consideration of this report was resumed in Committee of the whole Council by

Mr. TEALE, who proposed the necessity for insisting that candidates at final examinations should be tested practically on regional anatomy. The Visitors had observed that candidates at final examinations were often deficient in knowledge of this subject. Recommendation 80 of the Council expressed the terms of the motion, and he would modify his resolution to embody an emphasis of that recommendation.

Rev. Dr. HAUGHTON seconded the resolution.

The resolution, after a lengthy conversation between various members of the Council, was carried.

Mr. TEALE proposed the following resolution:—"That it is desirable that in every final examination for a surgical diploma, candidates should be required, as far as practicable, to perform operations on the dead subject, in conformity with the intention of Recommendation 44 of the Council."

Sir WM. GULL seconded the resolution.

Mr. MACNAMARA complained of the "milk and water" character of the resolution. The neglect already accorded to the recommendation of the Council referred to should teach the insufficiency of such a resolution. The difficulty as to subjects could be overcome, as it had been surmounted by the Royal College of Surgeons of England. Every student should be tested in operative surgery, as being a most important branch of surgical education. He felt that the Council should insist on every candidate for a surgical diploma being tested as to his capacity for operating.

Mr. MARSHALL objected to the idea that a man's power as an operator could be discovered from his performance of one or two operations on the dead body. Previous education on the subject could alone insure adequate response to the examiners' test. It was, however, impossible that every student could be adequately taught by practice how to operate, because of the paucity of material. Under existing circumstances the resolution could not possibly be carried out, though it was eminently desirable. It was of the highest importance to cultivate the schools rather than examinations.

Dr. CHAMBERS thought Mr. Marshall mistook the duties of examiners. They were to control education, and he thought it possible to judge from one or two operations how far a man had been taught operative surgery.

Rev. Dr. HAUGHTON, in view of the practical objections raised by Mr. Turner and Mr. Marshall, could not insist on the more stringent resolution. He was, nevertheless, convinced of the high importance of such a resolution if it could be carried out.

The motion was carried.

Mr. TEALE next moved the fifth resolution of the Visitors, to the effect that examination in operative surgery for every surgical qualification should be confined to such operations as any practitioner may suddenly be called upon to perform.

Prof. HUMPHRY deemed the resolution inexpedient. It would be better to leave matters as they stood. Many urgent operations could not be performed on the dead body.

Mr. TEALE said he had no desire to press the motion. He was satisfied with the discussion which had arisen.

The motion was then withdrawn by leave of the Council.

Mr. TEALE moved the sixth resolution:—"That the application of bandages and splints should be required in every surgical clinical examination."

Sir WM. GULL seconded the resolution.

Dr. WATSON proposed the withdrawal of the word "clinical."

The clause was passed.

Mr. TEALE moved that practical examinations in chemistry should, when feasible, be conducted in a laboratory.

Mr. TURNER wanted to know the meaning attached to "laboratory."

Rev. Dr. HAUGHTON would second the resolution with the omission of "when feasible."

Mr. TEALE said he intended to imply by "laboratory" a place where candidates could perform the analysis of substances under more favourable circumstances than surround examination at a table.

Mr. TURNER thought such an arrangement unnecessary. Appropriate tests collected on a table would suffice for the purpose of such examination.

Rev. Dr. HAUGHTON disagreed with Mr. Turner's view, and insisted that any practical examination in chemistry should be thorough, or altogether omitted.

Dr. PITMAN explained the mode in which the examination in chemistry was conducted at the Royal College of Physicians of London.

Mr. MACNAMARA insisted on the necessity for such practical examination, especially since the subject was one of ordinary medical education.

Dr. STORRAR said the University of London undertook to conduct practical examinations in every subject of education.

Dr. ACLAND thought the motion unnecessary.

The motion was carried.

In respect of the Visitors' conclusion that greater prominence to histology should be given by various examining bodies whom they considered to have been lax in this particular, it was recommended that the Council's Recommendation 42 should be reaffirmed, this dealing with the advisability of examining candidates in practical microscopy.

Mr. TURNER thought the opinions of the visitors as to the

amount and nature of knowledge of histology required from candidates should be expressed.

Rev. Dr. Houghton, Dr. Lyons, Mr. Simon, Dr. Watson, and the President, having spoken, Dr. Storrar urged that recommendation 42 covered the whole question in dispute.

Prof. HUMPHRY urged the Council to carefully consider ere it complicated the examination of candidates for diplomas by incorporating into it additional matters. He thought the existing recommendation met all requirements.

Mr. Macnamara and Dr. Pettigrew spoke, and

Mr. TEALE then read a modified motion to the effect that all candidates for licences to practise medicine and surgery should be required to recognise prepared preparations of normal and morbid tissues.

Dr. PETTIGREW seconded this, which was carried.

ORAL EXAMINATIONS.

Mr. TEALE said the visitors had given special attention to the causes of rejection of candidates. The numbers who failed varied at different places between one-third and one-half of all who presented. The very perfection of the machinery for examination at the Royal College of Surgeons might be the cause of improper rejections. It was notorious that many candidates failed in this examination who were the picked men of their own schools. This uncertainty was a serious drawback, and conduced to cramming and over preparation. It was possible that the impartial way in which the examination was conducted, each candidate being examined by four examiners, and known only by a number militated against success. The system of marking also might be regarded as tending against the candidates. The rigid adherence to the "time" standard of the College also was not in favour of the candidate. It served to enable examiners to judge ignorance rather than knowledge. The College might well take into consideration outside impressions regarding its examinations. He moved that the Council approve conclusion 10 of the visitors.

Mr. MARSHALL contended that the fleeting character of the visits paid to examinations by the visitors prevented them from forming correct opinions on the test they surveyed. The rejections at the Royal College of Surgeons primary examination amounted to 29 per cent. of the candidates; Cambridge rejected 43 per cent., Durham 34, London 44, Royal College of Physicians, Edinburgh 37, Surgeons 54, and in all the other bodies the percentage of rejections exceeded that at the Royal College of Surgeons of England. This would show that the charge of unfairness to candidates could not be maintained.

FIFTH DAY, SATURDAY, JULY 1.

VISITATION REPORT.

On the motion of Dr. PITMAN, the Council resumed, in committee, consideration of the Visitors' conclusion.

Rev. Dr. HAUGHTON considered that nervousness meant ignorance, and that any candidate who was nervous under examination was unfit to follow the profession. Referring to Mr. Marshall's enumeration of percentages, he said the number for Dublin University was 28, being thus less than that of the Royal College of Surgeons of England. He denied that a high percentage of rejections afforded any criterion of the excellence of the test; it only showed that candidates presented themselves without due preparation. He felt that 15 minutes *viva voce* examination was ample time to discover any man's fitness to pass; he could decide on any case in five, or at most ten, minutes. It was possible that certain examinations might be advantageously rearranged.

Dr. SCOTT ORR thought some latitude of time should be allowed to examiners. Limitation of time had long been followed at the Faculty of Glasgow and at Glasgow University, but it had been finally abandoned from the conviction that deserving candidates might possibly be rejected through nervousness. The rejections by Scotch corporations were mainly of men who were not educated at the centre of examination.

Dr. BANKS was strongly convinced that in many instances too short a time was given to "slow" men to enable them to make the best exhibition they could of the knowledge they possessed. He referred particularly to final examinations.

Dr. LYONS spoke to the difficulties experienced by every examiner in connection with the subject under discussion. Skilful examiners could rapidly estimate the capacities of candidates without any extended series of questions. There were men, however, of slow mind, who required careful treatment. Good examiners were exceedingly rare; bad ones, plentiful. He feared that education and examination were

progressing much more rapidly than the capacity of candidates. If education could be absolutely perfected, examination would be unnecessary. He trusted some such resolution as that before the Committee would be adopted.

Mr. MACNAMARA said it should be borne in mind that the 15 minutes' oral examination supplemented a previous written test, and was, therefore, sufficient for the purpose in view. He could determine in five minutes whether a candidate deserved to pass—ten minutes was always ample time. "Slow" answerers offered no difficulties, for even with them their attainments could be speedily ascertained. The exigencies arising when large numbers had to be examined necessitated the adoption of a time limit, and he never heard that rejected candidates complained of being too short a time under examination. In Ireland all candidates for licences to practise underwent two separate examinations, and obtained two diplomas. The Colleges of Surgeons and Physicians and University of Dublin were represented by the Visitors as not being on reciprocal relations; but this was hardly correct. Licentiates of the College of Physicians and M.B.'s of Dublin University were relieved from examination in Chemistry, Materia Medica, and Practice of Medicine, but were carefully tested in Surgery. He thought the Council would be wise to leave such details to the corporations, and regretted that the Visitors had entered on their consideration.

Prof. TURNER wished to know if, in the written examination referred to by Mr. Macnamara, each candidate wrote answers to the papers set by each of four examiners named in the appendix to the report.

Mr. MACNAMARA answered in the affirmative, the reason being that by giving each of four examiners a voice in rejections, the interests of public and students were alike considered.

Mr. TURNER pointed out the harshness of rejecting a candidate on the voice of one examiner only, who, should the answer he receives be very bad, can veto the candidate's further chance. He had tried both systems, that under the time limit, and that where discretion was permitted to the examiner, and he was convinced that the latter system gave more satisfactory results.

Prof. HUMPHRY admitted that he regarded good examinations as most important, and that by perfecting them the Council would be perfecting education. At the College of Surgeons a veto was given always by two examiners, never by one only. Candidates vetoed at one table were usually found to have failed elsewhere in the examination also. He himself was rarely wrong in his estimate as to who, of his own students who entered for the primary examination of the Royal College of Surgeons of England, would be successful. He considered the time limit had its advantages; a sharp mode of examination tended to banish nervousness; there were, nevertheless, certain disadvantages connected with the time limit; it prevented sufficient time being given to doubtful men, and for them the examiner should have latitude given him. Therefore he supported the motion.

Dr. PETTIGREW supported the motion.

Dr. HALDANE thought the question inappropriate for discussion by the Council. It had much better be left to the discretion of examining boards. Evidence was given by Prof. Turner that some bodies made the change themselves.

Dr. PITMAN said that the time limit had been abolished at the Royal College of Physicians of London because it had been found to involve waste of time in the case of good candidates, and to be unfair to medium men. He did not think nervousness always meant ignorance. It might be well to do as Dr. Haldane suggested, and not deal with the question at all.

Dr. QUAIN urged that latitude should be allowed to examiners.

In reply to Mr. Simon, Mr. MARSHALL said the number of cases reserved for further consideration at the Royal College of Surgeons was very small, only 3 or 4 per year. Of the rejections, 1 in 11 were rejected by the lowest obtainable number of marks, and the numbers rejected by veto were very small. The practice of the College really acknowledged the principle of the resolution.

Mr. SIMON dissented from the idea that the question was not important enough for the Council's consideration. Certainty could not be relied on in examinations held under the time limit system in cases of "slow" candidates. He had often seen men examined at the College of Surgeons concerning whom he could not himself say at the end of the ten

minutes they had been satisfactorily examined. He would vote for the resolution.

Dr. CHAMBERS supported the motion.

Sir WM. GULL felt sure that many men were rejected who ought to pass. The student ought to be more considered than he usually is when under examination. He supported the motion.

Prof. HUMPHRY explained that he did not deny that candidates might suffer from nervousness. He contended, however, that the sharp system at the Royal College of Surgeons favoured such persons.

Rev. Dr. HAUGHTON inquired whether the Visitors were of opinion that substantial injustice to candidates had been done through the operation of the time limit at certain examinations?

Mr. Marshall and Dr. Lyons having briefly spoken,

Mr. TEALE said that the Visitors had acted in accord with the directions given them by the Council. He did not think the figures quoted by Mr. Marshall were comparable. The "test" examination at medical schools sifted candidates for the primary at the Royal College of Surgeons. Dr. Gairdner was of opinion that absolute ignorance was too often assumed by examiners on the part of candidates, and that time was often essential to enable adequate knowledge to be shown.

The PRESIDENT eulogised the work of the Visitors, and adverted to the remarkable fact that a long and important discussion had taken place on a most anxious and serious question. He felt quite sure that many excellent men did fail to succeed under present circumstances.

The motion was then put and carried.

On the motion of Dr. Pitman, the Council then resumed.

THE PHARMACOPŒIA.

The Pharmacopœia Committee having presented their report,

Dr. PITMAN moved its adoption.

Dr. STORRAR thought that further information of the Committee's further intentions ought to be given. Such Committees ought not to take any definite step without consent of the Council.

Dr. PITMAN said the Committee intended to follow the lines of former Committees, and to call in outside expert assistance.

Dr. QUAIN explained that the Sub-Committee would appoint editors to report on necessary steps, and their conclusions would be reported to the Council, whose sanction would be preliminary to every action.

In reply to Mr. Turner,

Dr. QUAIN said expert aid would be obtained through "editorial" assistance from without.

Mr. Simon, Sir Wm. Gull, and Mr. Macnamara having spoken, the motion was carried.

UNQUALIFIED ASSISTANTS.

Dr. CHAMBERS moved the following resolution:—"That a Committee be appointed to consider the abuses which arise from the employment of unqualified assistants by registered practitioners, and to report to the Council whether any means can be adopted for checking these abuses."

Mr. BRADFORD seconded the motion.

Sir WM. GULL doubted whether the Council had any power to deal with the matter at all.

Mr. SIMON pointed out that it could do so, inasmuch as employment of unqualified men was a professional abuse, and the employers were therefore culpable. It was highly desirable the Council should register its opinion on this matter.

Dr. Aquilla Smith and Mr. Macnamara having spoken in support of the motion, it was carried.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Halifax 8; Cardiff, Norwich 12; Portsmouth, Leicester, Bradford 14; Birkenhead, Birmingham 15; Wolverhampton, Sheffield, Bristol 16; Huddersfield, Edinburgh, Blackburn 17; Leeds, London 18; Oldham, Salford, Newcastle-on-Tyne, Plymouth, Nottingham 19; Derby 20; Brighton 21; Hull 22; Sunderland, Dublin, Bolton 23; Glasgow, Liverpool 25; Manchester 27; and Preston 28.

ABSTRACT OF THE REPORT OF THE MEDICAL ACTS COMMISSION.

I.—GRANT OF MEDICAL LICENCES.

THE Act of 1858 would appear to have been passed rather in the interests of the general public than with a view to protecting the separate interests of the medical profession. Parliament was not prepared to enact that registered persons alone should practise medicine or surgery, but it seems to have been assumed that, if a statutory distinction were drawn between registered and unregistered practitioners, the public would know how to protect itself against unqualified persons.

The licensing bodies being nineteen in number, dissimilar in constitution, and conferring different titles, it was not to be expected, and not to be desired, that their examinations should be uniform in character, or even approximately equal in standard.

We think it fair to state that the large majority of the licensing authorities have shown a praiseworthy readiness to introduce improvements in their examinations. Since 1858 all the authorities have agreed to insist on a preliminary examination of each intending medical student in general knowledge prior to admission to medical study; and the examinations in science, and, in most cases, the practical examinations have been improved.

On the other hand, it has been stated in evidence, and especially by witnesses who have been engaged in private tuition, that not only do the diplomas and degrees of these medical authorities imply very different standards of skill and knowledge, but that in some cases the possession of a diploma affords no guarantee that the practitioner holding it possesses a competent knowledge of medicine, surgery, and midwifery.

Several distinct causes appear to us to lead to this result, such as the imperfections and low standard of some examinations; the fact that some examinations are injudiciously divided into parts, the first part of the examination of one corporation being accepted by another, as in the case of the Apothecaries' Hall of Ireland and the Edinburgh corporations: to which may be added the unsatisfactory manner in which the examiners themselves are in some instances appointed, as appears from the evidence laid before us by the representatives of the two Societies of Apothecaries.

Another prominent defect of the present licensing system lies in the fact that nearly all the medical corporations grant diplomas in medicine alone or in surgery alone. Further, even the diploma of the Royal Colleges of Surgeons of England and Ireland does not imply a knowledge of midwifery.

Again, new Universities will doubtless from time to time be created in the United Kingdom, each of which will, of course, lay claim to the privilege of giving a medical degree and of thereby becoming, if the present licensing system be continued, a licensing authority.

Moreover, were the present system continued, new Universities would claim not only to be added to the licensing authorities, but to send representatives to the Medical Council—a body generally allowed to be already too large, though the representation upon it of some of the licensing authorities (as, for instance, of Edinburgh University) is acknowledged to be, under the present system, disproportionately small.

With a view to preserving the principle of the present system, a proposal has been made that no limit should be fixed as to the numbering of licensing Universities and corporations, provided that in every case coadjutor examiners, sent by a central authority, be admitted by the corporation or University to its examining board. For this purpose it is claimed that it causes the least disturbance of existing interests, while ensuring that the Medical Register shall be, what it was intended to be, a record of those persons who have satisfied a State-recognised authority that they are duly instructed and practically competent in medicine, surgery, and midwifery. Having con-

sidered this proposal from every point of view, we are unable to recommend its adoption. The difficulty and expense of adequately inspecting so many examinations and of guaranteeing their efficiency would be great, and the difficulty in the way of a fair adjustment of the representation of existing interests and of the representation of new interests upon the General Medical Council would be almost insuperable.

The present system might also be preserved in another way. It would be possible to require that an examination, conducted on behalf of the State, should be the necessary preliminary to enrolment on the Medical Register; and also that such examination should be open only to those who had previously obtained a complete qualification by licence or degree from some chartered medical authority or authorities. It is urged that, by such an arrangement, the State would only so far interfere with vested interests as to exercise its right to test for itself the qualifications of those to whom it grants exclusive powers and privileges. It is represented that such a plan would tend to raise the standard of medical education by affording a public competitive test of the examination standard of each medical authority. It is further urged that the diplomas of the less worthy bodies would be less and less sought by a process of natural selection. To these arguments there is one powerful answer, that the general voice of the profession is opposed to any plan which will add a new examination; and this objection is based not only on the additional expense, but on the distraction of the students by two different examinations, of which the last would be, to them, the most important.

It is our opinion that the holding of a licence ought to be conclusive evidence of sufficient proficiency in medicine, surgery, and midwifery. After a long and careful inquiry, we have arrived at the conclusion that such a standard of proficiency can only be ensured by reducing the number of licensing authorities.

Our proposal, stated in general terms, is: that there shall be one medical Council, and that, in each of the three divisions of the United Kingdom, there shall be a Divisional Board, representing all the Medical Authorities of the Division; that the right of admitting to the Medical Register, and a general control over the proceedings of the Divisional Boards, shall vest in the Medical Council; and that, subject to such control, each Divisional Board shall, in its own Division, conduct the examinations for licence.

Our detailed proposals with regard to Divisional Boards are as follows:—

1. In each Division of the United Kingdom a Divisional Board shall be appointed, whose certificate shall be necessary for admission to the Medical Register.

2. Each Divisional Board shall contain one or more delegates of each chartered University and Medical Corporation, whether now existing or hereafter to be created.

3. The number and proportion of such delegates should, in the first instance, be fixed by Parliament; and provision being made for a decennial revision of the allotment of members, with a view to altering the proportion, if changes in the relative importance of the bodies hereafter render such alteration desirable; such revision to be made by the Medical Council subject to appeal to the Privy Council.

4. The members of the Divisional Board shall be elected from time to time for a term not exceeding five years, and shall be capable of re-election.

The duties and functions of each Divisional Board shall be—

1. To appoint members of the Medical Council.
2. To prepare regulations for a course of professional study and rules for examination.
3. To nominate from time to time the medical educational bodies, whose certificates shall be accepted as to sufficiency of education.
4. To take all necessary steps, by inquiry or otherwise, to ascertain the sufficiency of the education given in each medical school in the Division.

5. To appoint the examiners for the Divisional Board examinations, and to supervise those examinations.

6. To visit from time to time separate professional examinations conducted in the Division.

7. To take such cognisance as may be necessary of the preliminary examinations, and to keep a Register of the medical students in the Division.

8. To receive and act upon the reports of the examiners, and to report, after each examination, the result thereof to the Medical Council.

9. To make an annual report of their proceedings to the Medical Council.

We think it right that all proposals for regulations should proceed, in the first instance, from the Divisional Boards, as directly representing the professional and teaching bodies, but always subject to the subsequent approval of the Medical Council.

II.—“THE GENERAL MEDICAL COUNCIL—CONSTITUTION, FUNCTIONS, POWERS, AND PROCEDURE.—RELATION TO THE UNIVERSITIES, COLLEGES, AND MEDICAL BODIES, AND TO THE MEDICAL PROFESSION.”

The duties assigned by the Act of 1858 to the General Medical Council in connection with medical education and examination are of a limited character.

It is, in our opinion, clearly proved that the General Medical Council has rendered valuable services to the profession and to the public. It is to the General Medical Council that the universal adoption of a preliminary examination for intending medical students is mainly due. The Council has also elaborated and published full and detailed recommendations, which have had a very beneficial influence upon the education and examinations of medical students.

Further, it has instituted visitations, which, so far as they have gone, have had an excellent effect in improving particular examinations and generally raising the standard of examination.

We propose that the Medical Council shall consist of eighteen members, chosen for a term of five years, and eligible for re-election; of whom six shall be nominated by the Crown; two elected by the registered members of the Medical Profession resident in England; one by the registered members resident in Scotland and in Ireland respectively; four by the English Divisional Board, and two by the Scotch and Irish Divisional Boards respectively.

In our opinion, the Crown ought to make its selections on the ground of fitness alone, irrespective of nationality; and we would suggest, that one or two distinguished persons, not members of the Medical Profession, might with advantage be appointed.

The Branch Councils will in our opinion cease to be necessary, as the Divisional Boards will take their place.

The direct representation of the profession upon the Medical Council is a question which has been so long and fully argued that we feel it unnecessary to enter upon it further than for the purpose of expressing our conclusion. While we insist that the reason of the existence of the Medical Council is the interest of the public, we cannot but recognise the vital interest of the whole Medical Profession in the constitution of that Body. It seems to us highly important that the Profession should have full and complete confidence in the Council, and, seeing that the governing bodies of the Medical Corporations, which now elect members of the Council can hardly be said to represent the great majority of practitioners, we think it advisable to give the general practitioner an effective voice in the body which will be the principal authority of the Medical Profession. We see no reason to suppose that the members elected by direct representation will be less eminent than those nominated either by the Crown or the Divisional Boards.

Holding the opinion that the Medical Council ought to be as far as possible removed from individual influences and prejudices, we have proposed that the members representing upon it the Medical Authorities should be

appointed by the Divisional Boards, and no longer by single Universities and Corporations. It will be seen also that the proposed form of election does away with the difficulty in regard to representation on the Council, which, if the present system were continued, would arise from an increase in the number of Medical Authorities.

We propose that the Medical Council shall be the sole licensing authority.

The Medical Council will receive annual reports from the Divisional Boards of their proceedings. It ought also to be in general communication with the Boards, and it will be familiar with their opinions through the members sent by the Boards. The Council should also have power to visit any examinations, to make any inquiries, and to call for any information from the medical schools, the Medical Authorities, or the Divisional Boards.

In the event of a Divisional Board failing to perform its duties, the Medical Council should be empowered to act in its stead.

The Medical Council ought also to take proper steps to ensure, as far as possible, equality in curriculum and examination between the three Divisional Boards.

But while the Medical Council will thus be the supreme medical authority, and will exercise a general control over everything relating to medical licensing, we do not intend, or anticipate, that the Council shall be the executive, or even the initiating body in questions relating to medical education and examination. It will indeed be in the power of the Council to inform the Divisional Boards with regard to such conditions of education and examination as ought in its opinion to be of universal obligation throughout the United Kingdom; and, when the proposals of the Boards are submitted for approval, the Council will have the power of varying them as it may see fit. But the regulations will originate with the Divisional Boards, which also will be the executive bodies for administration.

III.—“COURSES OF EDUCATION.”

Although we have recommended that the Divisional Boards should prepare, and submit for the approval of the Medical Council, regulations for courses of study, we are of opinion that these should be only a general outline of what is necessary. It would be a mistake to introduce absolute uniformity into medical education. One great merit of the present system, so far as teaching is concerned, lies in the elasticity which is produced by the variety and the number of educating bodies. Being anxious not in any way to diminish the interest which the teaching bodies now take in medical education, or to lessen their responsibility in that respect, we desire to leave to them as much initiative as possible. In certain matters of general importance, such as the duration of study and the age at which a student should be permitted to practise, common regulations ought, we think, to be laid down; but we wish to record our opinion that nothing should be done to weaken the individuality of the Universities and Corporations, or to check emulation between the teaching institutions of the country.

IV.—“COURSES OF EXAMINATION.”

As we propose that in future a medical licence shall be given only after satisfying the examiners of the divisional boards, we have not thought it necessary to institute a minute inquiry into the examinations of the present licensing bodies. There is, however, a notable concurrence of opinion among the witnesses that the examinations of the Apothecaries' Societies have not been satisfactory, and opinions to the same effect have been expressed with regard to the Edinburgh College of Surgeons and the Glasgow Faculty of Physicians and Surgeons.

We agree in the opinion universally held by the witnesses, that every intending medical student ought to pass an examination in general education before entering on medical study. We are of opinion that the general scope of the examination should be defined by the Divi-

sional Boards, subject to the approval of the Medical Council; but that the conduct of the examination should be left to the Universities or such other educational or examining bodies as may be approved by the Medical Council.

During the course of medical study, professional examinations, other than the final examination next mentioned, ought, we think, to be held by examiners of the Divisional Boards. But we think also that power should be given to the Medical Council to accept the results of similar professional examinations conducted by the separate medical authorities, on being satisfied that such examinations are of a sufficient standard.

The final examination in systematic and clinical medicine and surgery and in midwifery ought, in our opinion, to be conducted by the examiners of the Divisional Boards in every case.

It has been strongly urged upon us by the Scottish Universities that, in their case, we should make an exception with regard to the final examination. In other words, it is proposed that they should retain their licensing power, on condition of admitting a certain number of examiners *ab extra*. To this request we much regret that we find ourselves unable to accede. To accede to their request would be to raise the Scottish Universities above all the existing medical authorities, and to leave to them alone the licensing power which we propose in every other case to take away. It must not, however, be imagined that we are transferring the licensing power to a central authority in which the Scottish Universities will have no share. On the Scottish Divisional Board the Scottish Universities will possess a preponderating influence which will be felt in many ways.

We consider that there should be power to hold the examinations of the Divisional Board at more than one place in each division of the Kingdom, if this should be found desirable.

Subject to the discretion of the Medical Council, examiners ought not to fill the office of examiner for a continuous period of more than from four to six years.

With a view to promoting approximate equality in the examinations, some of the examiners in each division may with advantage be selected from another division of the United Kingdom.

The fees to be paid by candidates for admission to the examinations of the Divisional Boards should be of such amount as will be sufficient to cover the cost of the examinations and the other expenses of the Divisional Board, and also to provide the sum required to compensate the medical authorities, or such of them as may be entitled to compensation, for any pecuniary losses they may hereafter sustain by reason of the abolition of their privilege of conferring a licence to practise; provided that the fee to be paid by medical graduates, or persons holding University certificates of having passed the professional examinations qualifying for admission to the final examination of the Divisional Boards, shall not exceed their proportion of the sum sufficient to cover the cost of the examination and other expenses aforesaid; but this reduction of fee is not to be allowed to a member of any University which obtains such compensation as aforesaid.

The Divisional Boards shall prepare schemes for the division of the surplus fees arising from the examinations applicable to compensation, which schemes shall be submitted to the Medical Council for approval.

V.—“GRANT OF MEDICAL DEGREES AND OTHER DIPLOMAS.”

If our recommendations be adopted, the statutory privilege of conferring a medical licence will no longer attach to the diplomas and degrees of the medical authorities, and in a certain sense their importance will be diminished.

We do not propose to interfere with the present powers of Universities or corporations to confer their titles, with or without examination. We think, however, that, in

the case of persons entitled to be registered, a discretion should be given to the Medical Council to permit these titles to be registered or not, as they see fit.

We think that each medical corporation ought to receive a statutory power to accept the certificate of a Divisional Board, in lieu of any examination, for admission to its lowest qualification, and that each University should receive a statutory power to accept the same certificate in lieu of its final examination in systematic and clinical medicine and surgery and in midwifery for primary graduation.

We cannot too strongly deprecate any interference with the examinations of the medical authorities for their higher titles. To higher titles we attach the greatest value, as a means of encouraging the acquisition of knowledge and skill in the medical profession.

It must, we think, also be conceded to every University, which has received, or shall hereafter receive, a charter, to give its own medical degrees; and we recommend that the Victoria University be in this respect placed, without delay, on the same footing as the older Universities.

In order to obtain admission to the Medical Register it has hitherto been necessary to possess the diploma or degree of one of the Medical Authorities; but if our recommendations be adopted, the certificate of a Divisional Board will in future of itself confer a right to registration on payment of the fees. Affiliation to a Medical Authority will thus no longer be necessary; but we hope and believe that medical men will not be contented with a bare licence to practise, and that they will continue to seek to belong to one or more of the Universities or Medical Corporations.

We do not propose to interfere with the discretion of the Universities or Medical Corporations in the matter of fees.

VL—"PRIVILEGES OF PRACTITIONERS:—RESTRICTIONS, DISABILITIES, AND PENALTIES."

We consider it undesirable to attempt to prevent unregistered persons from practising, but, at the same time, we think they should be prevented from representing themselves as being registered, or from assuming titles which would lead the public to believe that they are regular medical men. The assumption by registered persons of titles to which they have no right is an offence with which the Medical Council may deal.

We consider that prosecutions for offences under the Medical Acts should be undertaken in England by the Public Prosecutor, or by anybody with the assent of the Attorney-General; in Scotland by the Procurator Fiscal, or by anybody with the assent of the Lord Advocate; and in Ireland by the Crown Prosecutor, or by anybody with the assent of the Attorney-General.

The Association of Surgeons practising Dental Surgery ask that qualified dentists not on the Medical Register should be prevented from styling themselves "surgeon-dentists." We do not see our way to make such recommendation.

The British Dental Association have asked for direct representation upon the Medical Council. We cannot recommend that this should be granted.

The London School of Homœopathy has laid before us a petition praying for the establishment of a Homœopathic School. Their request does not appear to fall within the terms of the Commission.

The Medical Herbalists presented a petition. We are unable to recognise the justice of their demands, which strike at the principle of the Medical Act of 1858, by seeking to extend to unregistered persons all legal rights and privileges of registered persons.

On behalf of women, Mrs. Garrett-Anderson submitted to us a paper. In effect Mrs. Garrett-Anderson contents herself with entering a caveat against placing women in a worse position than they occupy at present.

If Divisional Boards be appointed as we have recommended, it appears to us only fair and reasonable that

women should be admitted to the examinations on the same terms as men, and should, if successful, be entitled to registration.

We do not propose to enter further into a much-disputed question, but it is only right to acknowledge the moderation with which the views of women have been laid before us, and the unwillingness of their advocate to retard medical reform by bringing forward extreme demands.

VII.—"FOREIGN DIPLOMAS."

The majority of professional witnesses are in favour of conceding the foreign and colonial demand. The evidence on this point, however, is by no means unanimous.

It is evident that there must be a considerable difficulty in discriminating between the diplomas given by different Universities abroad and in the colonies. We cannot, however, suggest a better solution of the difficulty than that proposed in the Government Bill of 1880. The duty of discriminating between the different foreign and colonial diplomas is thereby entrusted to the Medical Council; and safeguards are provided against the possibility of a British subject obtaining a foreign or colonial diploma merely for the purpose of avoiding the medical examinations in England, Scotland, or Ireland.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 5, 1882.

THE THIRTY-THIRD SESSION OF THE GENERAL MEDICAL COUNCIL.

It is satisfactory to be able to say that the present, the thirty-third session of the General Medical Council has been productive of a greater amount of beneficial work than it has been possible to accredit to it for many years. The first two days were, it is true, wasted, so far as any practical good resulting from the discussion which marked them is concerned, but the subsequent sittings have been chiefly devoted to a lengthy discussion of the report presented by the Visitors appointed to inspect the examinations conducted by the various licensing boards of the United Kingdom, and it is impossible to withhold a measure of praise at the substantial advantage likely to accrue from the proceedings of the Council in this connection. It is remarkable, too, that the deliberations on this report have exhibited a spirit of earnest desire on the part of a majority of the Council to set decisively to work in the direction of reform; in place of wasting precious time on subordinate topics, it has determinedly attempted to consider and to frame suggestions for the amendment of abuses which the Visitors have deemed it essential for them to bring into prominent notice in their report; and though when, at a later period, we

enter on a critical review of this document itself, we shall have occasion to point out its many shortcomings; we must nevertheless at once admit, that while dealing imperfectly with many subjects, it is, at any rate, successful in exposing certain leading deficiencies in the tests reported upon.

The President's address to the Council is just one of those productions which might have been expected from an official of Dr. Acland's capabilities. Impressive and polished, so far as diction is concerned, and couched in a tone of dignified defence, it may be regarded as very fitly serving the peculiar necessities of the occasion of its delivery. Threatened with somewhat sweeping reforms and reforms which the most obtuse perception is compelled to associate with inherent deficiencies, the General Medical Council just now occupies a position of peculiar difficulty. Barren of result though the curious report of the Royal Commission on the Medical Acts may be, it still cannot fail to direct especial attention to the performances of the central authority for the remodelling of which it makes particular provision. That the body of the Council is conscious of the importance attaching to its present attitude and performance has been manifest in the increased earnestness of its recent work, and it probably did not need its President's hint to enforce the appropriateness of such a display of zeal upon its members. Dr. Acland could not be expected to view with very great approval the proposals for changes in the *personnel* of the Council. In effect he gave expression to his views in this respect when he declared that "for his own part, he could not convince himself, after many years' observation and experience, that the principle on which the Legislature constructed the Council in 1858 was erroneous." With a loyalty to the cause of professional reform, however, which those who least agree with him will unhesitatingly admire and applaud, Dr. Acland adds, "Yet I would devote my utmost energies to bring about, at the earliest moment, the formation of any council which could be left undisturbed to use the powers which the Legislature might accord to it, and to work for the common purpose of promoting the steady growth of medical knowledge, as distinguished from medical politics, which belong to voluntary organisations, and not to a responsible Council of Education."

Not improbably the view which Dr. Acland takes of the duties of the Council is of a circumscribed nature, the limits set to it being indicated by the traditions familiar to himself, and arising strictly out of his own personal estimate of the Council's proper functions. This view does not accord with the broader conclusions of those who deem it right and proper that a General Medical Council should practically as well as nominally defend the true interests of medicine by assuming judicial functions in addition to merely regulative duties. It may be, indeed, that the difference of opinion within and without the Council on this point is the basis of that disagreement regarding the fitting constitution of the central authority which finds expression in the demand for, and the objections to, "direct representation." On this, however, it would be useless to enter further at the present moment.

The following passage from Dr. Acland's address contains the defence of the Council which it was incumbent on him to deliver in recognition of the Commissioners' Report. It will be accepted as a fair statement of nearly twenty-five years' labour:—"For now eleven years the Council has laboured under an abiding difficulty which it was powerless to remove. Parliament had in 1858 enabled all the licensing authorities of our profession to send to a common Council a representative. The authorities in England, Scotland, and Ireland at that time had in many respects conflicting interests. These had to be fought out in the Council, in continuation of contests which had resulted in the passing of the Act of 1858. Notwithstanding these difficulties the Council, in a very few years, produced a complete *Register* of the profession; exercised discipline which had never before existed; put an end to animosities between institutions; digested a national *Pharmacopæia*; created the efficient conduct of a central office, which was gradually collecting and diffusing information of educational value to the whole medical profession and to the country at large and brought about a marked improvement in education, general and professional. This is well illustrated by the fact that the Royal College of Surgeons of England has relinquished its examination in arts for examinations to be conducted by the national educational bodies in compliance with the strongly-expressed desire of the Council, that the same tests of general education as belong to the higher education of the country should be also applied to all medical students; and at the same time one of the older Universities agreed to establish special local examinations at the period of the year most suited to the circumstances of youths about to enter the profession of medicine.

"Among other things which the Council advocated and would have carried out in some form, under the pressure, no doubt, of Lord Ripon's Bill in 1871, was a fusion of the licensing bodies for examination purposes. But suddenly all progress was blocked by discussions on the constitution of the Council, carried on within the profession so persistently that I acknowledge with deep regret that justly or unjustly a doubt has been thrown on the wisdom of Parliament in having entrusted the education of our profession to the representatives of our old institutions, though it is by them that medical education and medical science have been raised to their present condition in great Britain. Had Lord Ripon's Bill passed, we should for the last ten years have been working a combined examination system of some description. No one would have been placed on the *Medical Register* who had not had a complete medical, surgical, and obstetrical education. Our whole force would have been harmoniously expended on perfecting that education and on solving the various problems which, in consequence of the vast progress of knowledge, year by year present themselves. As it is, we have necessarily been distracted by collateral discussions on Parliamentary Bills which have failed to pass, and we have been, without ceasing, impeded by the doubts and uncertainty attending deferred legislation."

The subject of a bill for the registration of midwives, the necessity of which we insisted on in a leading article

about 15 months ago, has at last come under discussion in the Council, and it is not improbable that the measure we have persistently urged will now be pushed forward, and the fruitful evils of the present system be effectually repressed.

Another important matter has been taken up by the Council, in consequence, we are bound to believe, of the action pursued by the *Medical Press and Circular* in exposing the serious evils of the Unqualified Assistant System, the last of a series of twelve articles on this subject having appeared in our columns a week ago. On the motion of Dr. Chambers, a committee has been appointed to consider the whole question, and to report on the means to be taken for checking the abuses to which the system gives rise. This committee, however, will not report until the next meeting of the Council, but it will strike most observers that its appointment is somewhat opposed to the opinion held by Dr. Acland as to the proper functions of the Council, the regulation of the practice complained of being really a matter of "medical politics," as apart from the "promotion of the steady growth of medical knowledge." It would therefore seem that even the Council takes a broader view of its own responsibilities than does its President.

With the most important part of the Council's work, the discussion on the Examination Visitors' Report, we must deal subsequently, as, at the time of going to press, the matter still remains under debate. We shall, however, discuss it somewhat fully in later issues.

PERSONATION.

THE resolution which the General Medical Council has adopted on the motion of Mr. Macnamara to appoint a committee for the purpose of inquiring into the possibility of personation at examination is well worthy of consideration now that new arrangements are being framed for the examinations of the future. There can be no doubt that there is an increasing danger of this sort of fraud, because of the tendency to generalise examinations. Indeed, we have this week an illustration of what may be attempted in this way in the case of the Irish medical student, for whose capture a warrant has been issued, as reported by us in another part of our issue. It may reasonably be suspected that this young man did not evolve the notion of passing by deputy from his own inventive genius, for it seems much more reasonable to suppose that he was emboldened to attempt to do so by the knowledge that others had done the same with impunity. There is really nothing but the fear of detection to prevent wholesale personation. Neither the Registrar of a College nor its Examiners can probably have the least knowledge whether the person who enters himself as Brown is really Brown, and it must necessarily be excessively difficult to render either the personator or the personated amenable to punishment unless one or the other turns Queen's evidence.

It may be possible effectually to guard against this proceeding by requiring the written application for examination to be countersigned by a clergyman or sworn before a magistrate who has a personal knowledge of the applicant, and who could forward it direct to the Registrar of

the College; but we may hope that the Committee of the Medical Council will be able to devise some satisfactory method of defeating the ingenuity of idle students and rapacious grinders.

Notes on Current Topics.

The Royal College of Surgeons of England and its Examinations.

DURING the debate in the General Medical Council on the report of the Visitors appointed to inspect examinations, Mr. Marshall, representative of the Royal College of Surgeons of England, took exception to statements made by more than one member of the Council, to the effect that the examinations of the College bore unfairly on candidates. In support of his proposition that the reverse was the case, he quoted from tables of the numbers of candidates passed and rejected by the various corporations to show that the percentage of rejections at the College, 29.4, was, in reality, with one exception, the lowest recorded. This certainly is a somewhat startling revelation, and one that might not have been anticipated. It should be remembered, however, that the action of "test" examinations at the schools is to reduce the number of "shaky" candidates to a minimum; and that by their operation only students who have shown their fitness to pass the ordeal are permitted to present themselves at the primary. Consequently, instead of a percentage of 29.4, a percentage of zero ought to be attained if no circumstances unfavourable to the candidate come into play during his examination. It is true that schools of the best reputation in many instances have now abolished the "test," but only so recently as to make its omission without much effect on the tables quoted by Mr. Marshall; therefore his argument in favour of the advantages obtained by candidates at the College loses all its force. Notwithstanding the fact that it is claimed for the College that its low percentage of rejections implies unusual fairness, in view of the difference between it and that of the Edinburgh Colleges, where the number exceeds 50 per cent., we are induced to ask for further information as to the manner in which these statistics are compiled. It is sufficiently notorious that not a few students who seek to pass the primary examination present themselves as many as two, three, and even four times. Now, if it should chance that at one institution every rejection goes to swell the percentage, while at another only the number of candidates rejected during the year is counted, it will be evident that such tables are valueless for comparison, and any argument based on them must be fallacious. Mr. Marshall was inclined to lay little stress on the complaints constantly urged against his College to the effect that well-prepared candidates could feel no certainty concerning the result of their examination. We trust, however, that he will take to heart Sir Wm. Gull's earnest assurances that these complaints were, indeed, very real ones, and well deserved attentive consideration. Those who have much to do with students do not need to be informed that the uncertainty of the College of Surgeons' test is a subject of common debate among them, and frequent expressions of

opinion to this effect are obtained from teachers also. Moreover, the "time limit," notwithstanding Mr. Macnamara's and Prof. Humphry's protest, does bear most unfairly on men not endowed with the iron nerve of examiners who can boast a dozen or twenty years' experience in the art of testing knowledge. There is something ludicrous in the assertion made by these two members of the Council, that nervousness is another name for ignorance, and it is to be hoped that they will disabuse themselves of the idea in favour of future examinees who come before them.

The Way Anti-Vaccinators are Made.

A COGENT illustration of the manner in which anti-vaccinators are manufactured has recently been afforded by Dr. George Wyld, in a letter to the *Echo*. In a preceding issue of the newspaper referred to an anti-vaccinatory letter entitled "The Animal Lymph Catastrophe at Georgia" had been published, in which an account was given of the evil effects following vaccination of persons in Georgia with calf-lymph. Dr. Wyld has investigated the particulars of the case, and finds that a Yankee speculator had kept some lymph in a moist state until decomposition set in, and then distributed the poisonous material, with the result that blood-poisoning was set up in all those persons who had been vaccinated with it. Dr. Wyld adds: "Fresh calf-lymph has been applied in millions of instances with perfect safety, and it is asserted that, so far as experience goes, not one death from small-pox has occurred in those so vaccinated. I would, therefore, most earnestly urge on fathers and mothers to beg of their medical attendants that calf-lymph only should be used in vaccinating their children."

Personation.

LAST week, in the Dublin Police Court, a medical student named Joseph Lavers was summoned to show cause why information should not be taken against him for having attempted to enter into a conspiracy with Dr. Norris, of Camden Street, London, to fraudulently pass his examination for his medical diploma. Mr. Murphy, Q.C., for the Crown, said he believed Mr. Lavers had no intention of appearing, so he asked for a warrant for his arrest. Lavers resided for some time at 22 York Street, and was attending an hospital in this city. It was his intention to become a duly qualified medical practitioner. But he appears to have encountered some difficulties in his studies, and to have been apprehensive of the result of the examinations. So he entered into communication with Dr. Norris, having become acquainted with that gentleman's name by articles which the latter had contributed to the *Lancet*. After making some preliminary inquiries, Mr. Lavers wrote to Dr. Norris, proposing that the latter would come over to Dublin and personate him, and pass his examination for him (Lavers). In the first instance Dr. Norris should receive £150 and afterwards £100. The diplomas should then be handed over to Mr. Lavers, who would go abroad to practise as a duly qualified medical man. Mr. Murphy read a couple of the letters, in the first of which, dated May 10th in the present year, Mr. Lavers said that he was anxious to become qualified, and that he was well up in practical work, but

that he was too delicate to read for the degrees. He wished to go as soon as possible to a warm climate, as he was constantly in bad health here, and offered the money to Dr. Norris to aid him in getting the diploma. Dr. Norris felt very much hurt by the proposition, and considered it an insult to himself as well as to the whole profession. He immediately communicated with the police, and hence the proceedings.

The magistrate gave the warrant for his arrest.

Boycotting the Profession in America.

It will be remembered that we some time ago commented on the fact that, at a meeting of the New York State Medical Society, a resolution was passed to the following effect:—"Members of the State Society, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity." At the time this was affirmed it was generally known that it had direct reference to the case of homœopaths, and throughout the States almost unanimous disapprobation was aroused at the action of the New York Society. Protests were freely raised against the resolution, and at the annual meeting of the American Medical Association these were practically embodied in a complaint addressed to that body, and a demand that admission should be refused to representatives of the errant society. The Judicial Council of the Association accordingly considered the objections, with the result that, "Having carefully examined the code of ethics adopted by the New York State Medical Society, the Judicial Council find in the said revised code provisions essentially different from, and in conflict with, the code of ethics of this Association, and therefore, in accordance with the provision of the ninth by-law of this Association, decide *unanimously* that the said New York State Medical Society is not entitled to representation by delegates in the American Medical Association." The announcement of this conclusion was received with prolonged cheering by the Association, which, to the number of 863, met at St. Paul from June 6th to the 9th last; it is a distinct utterance of the opinion in which temporisers with irregular practice are regarded by the respectable section of American practitioners. There is a good opportunity now for a similar course of action on the part of the American Association's British prototype, for, if we remember rightly, one of the branch associations in this country has adopted a similar elastic code to that approved by the New York Society. It is certainly highly desirable that opportunity should be taken of this occurrence to follow the example set in America, and emphatically protest against the unwise playing with danger unfortunately advocated at the last meeting of the British Medical Association.

NEGOTIATIONS for the establishment of a new medical school in New York City, under the auspices of the Cornell University, are progressing. The move was started by the members of the medical department of the University of New York who recently seceded from that body.

The Royal Commission and the Scotch Examining Bodies.

It is not to be expected that the Scotch corporations would relish the suggestions of the Royal Commissioners on the Medical Acts, or that Professor Turner would remain silent at this important crisis in the history of these bodies. Unfortunately for his clients, Professor Turner's advocacy is somewhat weakened by several important considerations. There is a large spice of the *egomet* in his assumed blindness to the badness of a system that has few, if any, defenders outside Scotland. Let us try to place the facts of the case clearly before our readers. It is well known that a student may obtain from a Scotch University two degrees which entitle him to place his name on the Register for a sum of money which he would be obliged to pay to any of the large hospitals in London for his education alone. Due to this cause, and to the care in teaching which has always characterised the Edinburgh School, and which is still maintained, large numbers of students are constantly repairing to Edinburgh to prosecute their medical studies. The fees from the students find their way into the pockets of the professors, who, in many cases, have discovered many ingenious artifices to make these as large as possible, one of these being a judicious application of the old priestly device of delivering certain esoteric doctrines, thus compelling students to attend their classes so as to become acquainted with them for examination purposes. It can easily be seen that, if the power of the Universities to give degrees, which are also licences to practise, be taken away from them, the classes will certainly be decreased in numbers. There is this, also, to be said—that the degrees will be of less value as a guarantee of sound general information or higher culture than they are now, for the professors will still be the examiners, and a graduate will simply be a living compendium of professional crotchets. This difficulty with regard to the Universities would not be felt in the case of the corporations. These bodies are in reality the cause of all the discontent which the profession has felt as to the existing state of affairs. Professor Turner's advocacy of them is only intelligible on the ground that he may feel that the corporations cannot be got rid of, and the Universities allowed to remain, and therefore he is compelled to defend them to save the Universities. Scarcely any one will be found to deny the statement that the methods of examination in the past, if not now, have been as bad as bad could be, and that a process of underselling the English corporations was as systematic as it was barefaced. Even now these colleges will accept of almost anything sooner than allow an intending candidate to pass by them. Anatomy may be passed here, physiology there, and chemistry anywhere, so long as the final, including the primary, fee is paid. At the College of Surgeons an intending candidate may be examined in midwifery or medicine by a dentist or by an examiner whose competency for the task is shown by the fact that for the last few months he has been known to have purchased largely of the "Aids Series." While the College of Physicians has in wiser moments been trying to meet the wants of the times, the College of Surgeons has contented itself by continuing in its old ways, waiting quietly to

die, or be forced out of existence. With regard to the Glasgow Faculty, all that can be said of it is that it gets all that Edinburgh cannot pass.

St. Peter's Hospital for Stone.

WE doubt the propriety of the decision which induced the governing body of this hospital to invite H.R.H. Prince Leopold to the new building on Thursday last for the purpose of declaring it "open;" and we can only hope that many poor patients in the country may not have been induced by the announcement in the lay press to take a journey to London in the expectation of being received within its walls, as several weeks must elapse before it is free of workmen. Of the necessity for a special hospital for stone it is not our intention here to speak; nor do we deny that good work has been performed in the little building where it was first started in Berners Street; our purpose is rather to condemn the cruel system of declaring places open, especially hospitals, when in such a manifestly unfinished state. Of the new building itself or its adaptability to requirements, it is of course too early to speak, with no more than bare plaster walls before us: externally it is a handsome structure of red brick, in Queen Anne style of architecture, the total cost of which will, we understand, be about £13,500, added to which there will be the cost of fittings, furniture, and other extras. The committee estimate that when all is accomplished, about £3,000 will be required beyond the funds in hand, and as there are several promises, and public attention has been prominently drawn to the institution by the presence of Royalty at the formal opening, there is every reason to expect that it will start free of debt. This result is mainly due to an anonymous gift of £10,000, added to which, a bevy of young ladies presented purses to Prince Leopold, amounting to over £1,200. Of the ceremony little need be said, that having been already fully described in the lay press. H.R.H. gracefully performed what little there was to do, but it must have been with a feeling of grim irony that he pronounced the words which were put into his mouth—"I declare this hospital open."

The Registration of Foreign Diplomas.

IN connection with the recommendations on this subject which are to be found in our Abstract of the Report of the Royal Commission on the Medical Acts the following is interesting:—Dr. Reeves in an address before the West Virginia Medical Society, says: "By her varied supply of diploma mills, Ohio is probably entitled to the greatest distinction. Any sort of a diploma, and gauged in price to suit purchasers, may be secured without trouble, expense, and the farce of the applicant." As illustrating the bad faith of the American medical colleges, he gives the following illustration:—An applicant for a medical certificate came before the district board at Wheeling, and failed to pass a satisfactory examination within the meaning of the law. Ten days later he knocked at the door of the graduating class of the Columbus Medical College, and was admitted. Within one month from that time he was graduated, and at a brilliant display at the Opera House he received his diploma. In the same

graduating class was one man "who did not know what the iris was, nor the pupil; could not locate the mitral or tricuspid valves; placed the valvulæ conniventes in the brain, and the ileo-cæcal valves in the rectum." As Dr. Reeves is connected with the State Board of his State, he is in a position to know of what he speaks.

DR. LAFFAN has been elected Chairman of the Cashel Town Commissioners for the ensuing year.

DR. W. B. CARPENTER, F.R.S., is announced to deliver the next Lowell lectures at Boston, U.S.A.

DR. JOHN POPHAM, of Cork, has been presented with an address and piece of plate on the occasion of his leaving that city after a residence there of nearly half a century.

THE Professorship of Anatomy in the Harvard Medical School has had but three incumbents in the century of its existence—Dr. John Warren, Dr. John Collins Warren, and Dr. Oliver Wendell Holmes.

THE highest annual death-rates per 1,000 in the large towns last week from diseases of the zymotic class were:—From whooping-cough, 1·8 in Sunderland and 1·7 in Bristol; from measles, 2·6 in Hull and 2·3 in Bradford; from scarlet fever, 1·3 in Derby and 1·0 in Blackburn; and from "fever," principally enteric, 2·1 in Preston and 1·6 in Portsmouth. Of the 31 deaths from diphtheria 19 occurred in London, 6 in Glasgow, and 2 in Portsmouth. Small-pox caused 10 deaths in London and its outer ring of suburban districts, 3 in Nottingham, and 3 in Leeds.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 33, Bombay 22, Madras 29; Paris 25; Geneva 18; Brussels 20; Amsterdam 25, Rotterdam 24, The Hague 20; Copenhagen 28; Stockholm 22; Christiania 19; St. Petersburg 48; Berlin 29; Hamburg 25; Dresden 28, Breslau 33, Munich 35, Vienna 28, Prague 29, Buda-Pesth, 37, Trieste 21, Rome 29, Naples 35, Turin 28, Venice 29, Alexandria 46 (including 10 which resulted from wounds inflicted during the riot of 11th June), New York 29, Brooklyn 23, Philadelphia 20, and Baltimore 23.

At a meeting held at the Langham Hotel on Wednesday, June 28, Dr. Farquharson, M.P., in the chair, it was unanimously resolved to present a testimonial to Mr. Ernest Hart, M.R.C.S., in recognition of his eminent public and professional services, and that an appeal for subscriptions should be made to the medical profession and the general public in support of the movement. It was further agreed that the testimonial should take the form of a portrait of Mr. Ernest Hart, to be presented to Mrs. Ernest Hart. Mr. Spencer Wells, F.R.C.S., was appointed treasurer; Mr. Arthur Myers, Surgeon to the Coldstream Guards, and Mr. Noble Smith, 24 Queen Anne Street, London, W., were appointed hon. secs.; and an executive committee, with power to add to their number, was nominated.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SURGEONCY TO THE QUEEN IN SCOTLAND.—We have to congratulate Dr. Patrick Heron Watson on his appointment as Surgeon to Her Majesty in Scotland, *vice* Professor Spence, deceased. Dr. Watson has well deserved this evidence of the Royal favour, for, besides his large general practice, he is a most skilful surgeon and bold operator.

SURGEON TO THE EDINBURGH TRAMWAY COMPANY.—We hear that Dr. Littlejohn, the Medical Officer of Health for Edinburgh, has been appointed to the above-mentioned Company. In view of the late scandals connected with the Company, we hope that our information is incorrect, for it is difficult to see how Dr. Littlejohn could well act as Surgeon to the Police and to the Company as well. Surely the interests of the two appointments are not identical.

THE EXTRA MEDICAL MURAL SCHOOLS IN SCOTLAND.—We hear that since the publication of the Report of the Royal Commission on the Medical Acts, proposals have been made with the object of bringing about a coalition of the Edinburgh and Glasgow Extra-Mural Schools for their mutual benefit and protection. These schools have long been in an unsatisfactory condition, for although the Colleges compel each lecturer to undergo a special examination in the subject taught, and demand fees for the same, no further interest is taken in the welfare of the school. In Edinburgh the school is supposed to consist of licensed teachers, each of whom pays three or four pounds a year to one of the lecturers, who acts as general advertising agent. The "school" meets two or three times a year to prepare the "Bill." Apart from this the lecturers teach in several buildings, and issue private bills throughout the town. In some cases these bills are addressed to the general public as well as to the students, for we find proposals to analyse water, beer, sweets, and other "breadstuffs" at the shortest notice, and presumably on economical charges. It is time that the Colleges stepped in and put matters on a better footing. They should be teaching as well as examining bodies, which would then place them on the same footing as the Universities. As far as examining candidates, the Government is quite as capable of doing so as any corporation in existence.

DEATH UNDER PECULIAR CIRCUMSTANCES AT GLASGOW.—As the result of what the newspapers have called "a horrible outrage," a boy, aged about 11 years, died recently at the Royal Infirmary, Glasgow. The newspapers seem to have discovered by experience that by debasing representations of humanity the public mind is brutalised, and their circulation thus increased. It seems hopeless to expect a higher *morale* from the daily press. The death of the poor boy in question was due to the accidental thrusting of a red-hot iron into his rectum. As represented in the newspapers, the public were led to infer that the victim was seated over an aperture, from under which another boy deliberately and diabolically thrust a red-hot iron into the victim's rectum. As the result of an examination of the locality, and information derived direct, we are pleased to be able to state that such was not the fact. In one of the pavement flags over the workshops underneath there is a circular hole, about an inch and a-half in diameter. If this hole were covered it would be impossible for any person underneath to say whether there was any person above. That boys congregated there, and were there on this day playing, was well enough known to the two boys accused of the crime. It occurred to one of them, it appears, for the purpose of "a lark"

—certainly an unjustifiable one—to heat a poker in the fire and to thrust it through this hole, when, by a marvellous accident, it seems to have penetrated the rectum of the victim. It appears, then, quite conclusively that the guilty boy had no idea where the poker was being thrust into. This is a sufficiently melancholy accident, no doubt, but the alleged brutality of the occurrence disappears on this view of the facts. The representations which appeared in the Glasgow newspapers were in the highest degree reprehensible.

THE CHAIR OF SURGERY AT EDINBURGH.—The Curators of the University of Edinburgh met on Wednesday last with reference to the vacancy in the Chair of Surgery caused by the death of Professor Spence. It was resolved to hold another meeting in July, and it is requested that intending candidates transmit applications, accompanied by any testimonials they may desire to submit, on or before July 10th, to the following gentlemen, who now constitute the Curatorial Board, viz.:—The Lord Provost, Sir Alexander Grant, Bart.; Lord Kinnear, Mr. Campbell Swinton, Mr. Duncan McLaren, Bailie Colston, and Mr. John Boyd, and also to Mr. R. Bruce Johnston, W.S., honorary secretary. The candidates already announced are Dr. Heron Watson, Mr. Joseph Bell, Dr. John Duncan, and Mr. John Chiene. In professional circles, Mr. Chiene seems to be the popular candidate. Dr. William McEwen, of Glasgow, is said to have offered himself as a candidate.

THE PROPOSED UNIVERSITIES EXECUTIVE COMMISSION.—At a meeting of the Committee appointed by the General Council of the University of Edinburgh with relation to the proposed Executive Commission on the Scotch Universities, held on Friday last, the following resolution was passed:—“The Committee regret to observe that it has been inferred from recent statements that the Government see no immediate prospect of bringing forward a bill for appointing an Executive Commission on the Scotch Universities; but, while fully recognising the propriety of not introducing a bill of the kind until there is a reasonable opportunity of carrying it through, the Committee at the same time feel very strongly the extreme desirability of early action, and venture to express a hope that such an opportunity may still be found during the present session.”

Correspondence.

THE ETHICS OF COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The medical question of the value of vaccination is one upon which most medical men have made up their minds; the moral question of the compulsory enforcement of vaccination is one that has received but scant consideration. The hon. member for Leicester, Mr. P. A. Taylor, M.P., has repeatedly invited the attention of Parliament and the public to the subject, but both have hitherto turned a deaf or unsympathetic ear to his entreaties.

The question, however, is one worthy of discussion, and is to be settled not by impassioned declamation, but by an impartial analysis of the subject, not by an *argumentum ad populum*, but by an appeal to the common principles of ethics. On the one hand we hear that vaccination is the greatest blessing ever conferred upon mankind, that unvaccinated persons are social nuisances, and that anti-vaccinators ought to be suppressed like noxious vermin.

“The Vaccination Acts rob me of my parental rights, urge me to sin against my conscience, and make me bear the risk of polluting my child's blood, while at the best they confer a doubtful benefit,” the hot-headed anti-vaccinator replies.

What has our morality to say to these two diametrically opposed opinions? The foundation of our social relations is what is known as the law of equal liberties. Every man has a right to exercise his liberty to the fullest, provided he does

not interfere with the liberty of his neighbour. The infringement of the rights of others is the only limit to be placed upon the rights of each.

Now, the vaccinator claims this principle as the foundation of the Compulsory Act. If anyone transgresses the law of equal liberties, he says, it is surely he who by allowing his children to remain unprotected, permits them to disseminate small-pox at their own sweet will. Small-pox, he argues, is a most infectious disease; all are liable to it; in vaccination we have an all but certain protection; to neglect this safeguard, then, is to endanger the health and lives of the rest of the community, or as Sir William Gull puts it, it “would be much the same thing as to take a fire brand and push it into an arsenal of gunpowder.”

Superficially viewed this style of argument has an air of plausibility about it; and it would seem that compulsory vaccination is a necessary corollary from the law of equal liberties. Further examination, however, will prove such conclusions to be erroneous. In the first place it is evident that to assert that the unvaccinated can endanger their vaccinated neighbours is a virtual surrender of the question—it implicitly denies the efficacy of the prophylactic it seeks to enforce. If the unvaccinated only endangered themselves by their folly they might justly be left to self-extinction; policy which must eventually bring about the consummation which is so devoutly wished for, a community entirely protected by vaccination or previous small-pox. To this it is at once replied, that if the neglect of vaccination *did* endanger only the individual himself, the State would not be justified in interfering, any more than it interferes with the incurring of a variety of other voluntary risks, but that the Vaccination Act deals not with adults, responsible men and women, but with helpless and innocent children; and it is the duty of the State to see that their lives are not jeopardised by their neighbours' omissions.

This position, too, appears at first sight unassailable; but it is evidently based upon the gratuitous and illogical assumption, which is this:—That an unvaccinated person is *ipso facto* in a state of small-pox infection, a “focus of contagion,” that he carries small-pox germs in his person or pockets, and that he is all life long in a state of chronic variola. Now, an unvaccinated person either has small-pox or he has not. If he have it he is just as liable to communicate it to others as one who contracts small-pox after vaccination, for everybody knows the most discrete variola is as contagious as the most confluent. His exposure in public under such circumstances is sufficiently guarded against by the Public Health Act. If, on the other hand, he have not got it, he is no more able to impart small-pox to others than a man can give what he has not got, or than the most thoroughly and efficiently vaccinated and re-vaccinated.

Those who argue thus commit the absurd mistake of confounding the liability to a disease with the disease itself, and would leave people to infer that the liability to a disease is contagious, which is simply ridiculous.

However strange, then, it may appear, and however much at variance with current notions it may seem, nevertheless, if we abide by the loss of equal liberties, and if we reject the irrational and untenable supposition that an unvaccinated person is *per se* a danger to society, we must conclude that the compulsory enforcement of vaccination is morally unjustifiable, and that in this, as in so many other cases of “parental” legislation, the State has exceeded its function and has sacrificed the liberty which it should seek to secure.

Your obedient servant,
W. J. COLLINS, M.B., B.S., B.Sc. (Lond.).

[Our correspondent assumes the medical value, but assails the legal compulsion of vaccination; hence the question becomes narrowed in scope. He seems to us to have quite missed the point when he supposes the view to be held that an unvaccinated person is a danger to society *per se*; it is not because he is unvaccinated that he is a danger, but because being unvaccinated, he is a *potential* source of infection to others. It must also be borne in mind that the unvaccinated who get small-pox endanger the unvaccinated who are exposed to the infection proceeding from them; it is not a question of the unvaccinated endangering the vaccinated (the danger of post-vaccinal small-pox in a duly vaccinated subject being infinitesimal), but of their spreading the dis-

ease amongst others similarly unprotected. The State, relying on the vast difference in the severity and fatality of post-vaccinal and natural small-pox, conceives it to be its duty to endeavour to place the community in such a position that, when an epidemic arises—whether by importation or in other ways—there shall both be as few members of it as possible unprotected (and, therefore, liable to a severe and fatal form of the disease), and also a minimum number free, by multiplying the centres of infection, to become sources of danger to other similarly unprotected persons with whom they may come into relation.—Ed.]

Royal College of Surgeons, Ireland.—The annual distribution of prizes to the successful students of this College took place on Tuesday, June 22nd. The chair was taken by Dr. Barton, President of the College, who, after a few preliminary remarks, distributed the prizes as follows:—First Prize—Senior Class, value £10 and a gold medal. Won by Mr. Austin N. Cooper. Second Prize—Senior Class, value £10. Won by Mr. Mayner L. Dutch. First Prize—Second Class, value £12. Won by Mr. William L. Simmes. First Prize—Junior Class, value £10. Won by Mr. George E. Greene. Second Prize—Junior Class, value £5. Won by Mr. Richard R. Fetherstone.

University of Durham.—The following practitioners of 15 years' standing have satisfied the Examiners for the Degree of M.D.:—

Adams, Josiah Oake, F.R.C.S.
Alexander, John, L.R.C.P.
Cowen, Philip, M.R.C.S.

Moore, Harry Gage, L.R.C.P.
Sanders, Richard, M.R.C.S.
Smith, Solomon C., M.R.C.S.

The following candidates have passed the ordinary examination for the Degree of M.D.:—

Cheestham, Walter Henry, M.B.
Coley, Frederic Collins, M.B.
Dowding, A. W. Woodman, M.B.
Giles, Bernard Faraday, M.B.

Hatton, George Stokes, M.B.
Mears, William Pope, M.B.
Porter, William Smith, M.B.
Roué, William Barrett, M.B.

The following gentleman has passed the Second Examination for the Degree of M.B. (Honours, Second Class):—

Price, William Elliott, M.R.C.S.

The following have likewise passed the examination for the Degree of M.B.:—

Beasley, Wm. Crump, L.S.A.
Bair, Charles Samuel.
Greenwood, Fredk., M.R.C.S.

Irvine, James Robert.
Milburn, Charles Henry.
Vise, Christopher, M.R.C.S.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. M. (Tiverton).—In your zeal for the "honour of the profession" we think you have taken a wholly mistaken notion of its meaning in the present instance; we are sorry, therefore, that we cannot assist you in attacking a legitimate object or individual.

INCORPORATION OF THE PARKES MUSEUM.—The Parkes Museum, which was first instituted in 1876 as a memorial to the late Dr. Edmund Parkes and in order to promote the health of the community for which Dr. Parkes so successfully devoted the best years of his life, was formally incorporated on Wednesday last, June 28th. The Museum has been temporarily located in University College, London, since its establishment, and negotiations are now being made for acquiring a permanent building in a more central position. The following are the officers elected for the ensuing year:—Treasurer, Prof. Berkeley Hill, F.R.C.S.; Secretary, Mr. Mark A. Judge; Hon. Solicitor, Mr. Basil Field.

A PROVINCIAL PRACTITIONER.—We have seen the prospectus, and agree with you that it is a mistake.

THE NON-ALCOHOLIC TREATMENT OF DISEASE.—From the ninth annual report of the London Temperance Hospital to hand, it appears that since the opening of the Hospital, October 6th, 1873, 1,354 in-patients have been treated, of whom 749 were dismissed cured. The deaths were 61. The out-patients treated have been 10,478. The new buildings opened by the Lord Mayor in March, 1881, afford accommodation for 51 in-patients, and the number of these treated in the last year has been nearly threefold the average of the preceding years. The non-alcoholic treatment has been so successful that the managers state it has had the effect of considerably reducing the quantity of alcohol prescribed in some other hospitals.

DR. W. C. (Cyprus).—Letters to hand; hope to be able to refer to the subject in our next. We consider you have been unfairly used by the Government, and shall not fail to bring the matter before the proper authorities. On the second matter we will make inquiries and inform you of result by private note.

MR. KIRKLAND.—We do not prescribe in these columns. If you are too poor to pay for the advice of a medical man—of whom you must have several near you—we can only suggest that you present yourself at an hospital and be treated as an ordinary hospital out-patient. We fail to see the logic of your argument.

A STUDENT.—The matter was postponed indefinitely; no further announcement has yet appeared, so that we cannot assist you.

MR. HENRY HERTFORD (Paris).—By the term slight refreshment it was intended to be conveyed that something in the way of food should be taken which, while not overburdening the stomach, would yet prevent the evil effects of bathing in a fasting state. A cup of coffee (not tea), or glass of milk with half a round of dried toast, or a slice of bread-and-butter, is all that is required. We cannot approve the plan of taking stimulants at such a time.

DR. F. M.—Many thanks for suggestions, and for the offer contained in your letter. If the necessity arises you shall be consulted before any definite steps are taken.

MR. JAS. FANSHAW.—The numbers were obtained after lengthened inquiries, and are the result of much labour and investigation. You can accept them as thoroughly reliable. Any assistance that we can lend you in the prosecution of your task we shall be happy to render.

A STUDENT cannot do better than consult the translation of Casper's work contained in the New Sydenham Society's Series. We believe that two of these volumes are out of print, but they may probably be obtained through a dealer in second-hand works. The "Manual" is now ready.

R. L.—The case is by no means unique, though of sufficiently uncommon occurrence to make its publication desirable. Diffuse aneurisms present many features of interest, and you have done well to keep careful record of the progress of the case under your care.

MR. FREDERICK JONES.—The Council will consider the circumstances, and by the time this reaches you a decision will have been pronounced. We cannot pretend to prophesy the result.

GUY'S.—We were not aware of the fact. Will you forward further particulars? The information at hand is too slight to be of any practical value.

H. S.—FEES TO MEDICAL WITNESSES.—Under the Attorney-General's rule a medical Crown witness at Sessions held elsewhere than the town in which the witness resides is entitled to £2 2s. fee, irrespective of distance, and the amount of travelling expenses actually paid; also 15s. a night hotel expenses if necessarily incurred.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At the annual general meeting on Friday next, at 8.30 p.m., the following papers will be presented:—Mr. Oglesby, "On Miner's Nystagmus." Messrs. Lang and W. A. Fitzgerald: (1) "On a Case of Homonymous Insular Scotomata;" (2) "On the Movements of the Eyelids in Relation to the Movements of the Eyes."—Dr. Bralley, "On the Tests of Vision for Service at Sea." Dr. Bralley will also show Charts by Joy Jeffries and Magnus for Educating the Colour-sense.—Mr. Rudall, "On Micrococci in the Eyeball."—Mr. Snell, "On Acute Glaucoma caused by Atropine and cured by Esferine."—Card and Living Specimens at 8 o'clock.—Dr. Bralley: (1) Peculiar form of Cyclitis; (2) Detachment of Pars Ciliaris Retinae.—Dr. Stephen Mackenzie: Sections of Retinal Hemorrhages.—Mr. Lindsay Johnson: (1) An Ophthalmoscope; (2) Appliance for Adjusting Lenses.—Mr. M'Hardy: Sequel to a Case of Black Cataract.—Mr. Stratfield: Living Specimen.

Vacancies.

Belmullet Union, Knocknallower Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health Election, July 10th.

Cambridge County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to be addressed to the Clerk to the Visitors on or before July 14th.

Central London Sick Asylum District.—Assistant Medical Officer. Salary, £100, with board and residence. Applications to be addressed to the Clerk to the Managers, at the Asylum, Cleveland Street, Fitzroy Square, London, not later than July 17th.

St. Thomas Union, Devon.—Medical Officer and Public Vaccinator. Salary, £90, including the usual extra fees. Applications to be sent to the Clerk on or before July 18th.

Births.

CONSTABLE.—June 27th, at 127 Kennington Park Road, London, J. C. Constable, M.D., of a daughter.

FENN.—June 28th, at Diss, Norfolk, the wife of C. D. Fenn, M.R.C.S., of a son.

HUGHES.—June 24, at Boyne Cottage, Navan, the wife of Surgeon-Major J. H. Hughes, M.D., A.M.D., of a man.

PALMER.—June 23, at the County Infirmary, Armagh, the wife of J. Mansergh Palmer, F.R.C.S., of a son.

Deaths.

BREDIN.—At his residence, 181 Great Brunswick Street, Dublin, Hall Bredin, M.D., aged 80 years.

COPE.—June 19th, at High Cross Street, Leicester, Walter H. Cope, M.R.C.S., aged 47.

HARRIS.—June 25th, at High Street, Old Brentford, Richard Harris, M.R.C.S., aged 41.

LEWIS.—June 25th, at 120 Drummond Street, London, N.W., H. Harman Lewis, M.R.C.S., aged 54.

LING.—June 28th, at Abbotford, Torquay, E. Clayton Ling, M.R.C.S., of Aldborough, Suffolk.

MURDOCH.—June 29th, at Bunedin, New Zealand, Anne, wife of Jas. Murdoch, F.R.C.S. Ed., and elder daughter of Professor Blackie, of Edinburgh. (By Telegraph.)

REID.—June 20th, at Hankow, China, Arthur G. Reid, M.D., second son of the late Arthur Reid, Banker, of Fochabers, N.B.

WILCOX.—June 23rd, at his son's residence, Warminster, Charles Wilcox, M.R.C.S., of Southsea, aged 74.

A Course of Lectures

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIA- THESIS IN RELATION TO SURGICAL DIS- EASE.

*Delivered at the Royal College of Surgeons of England,
June, 1882.*

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and
Surgery, Royal College of Surgeons, England.

(Continued from page 8.)

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—I hope I have made it sufficiently clear that I am not purposing to trouble you with any list of the idiosyncrasies; as well for your relief as my own exculpation, it is perhaps desirable that I should again make this statement. What I said about egg poisoning in my last lecture was intended to suffice as an illustration of what is possible, indeed, I would suggest not infrequent, in reference to a whole group of food idiosyncrasies. The same remark applies to the somewhat detailed discussion on the susceptibilities in reference to tobacco. We are engaged in the examination of the laws of idiosyncrasy, and not in any attempt to record exhaustively its facts. I shall bring before you no more narratives of cases or statements as to facts than may seem absolutely necessary to illustrate the general laws to which we refer. In Monday's lecture we glanced briefly at certain peculiarities of structure which are sometimes met with in external parts which are congenital and hereditary. For these I propose the name of structural idiosyncrasies, and asked that we should apply the knowledge that we can easily gain respecting them to those which are much more obscure, from the fact that they are betrayed only by derangement of function. I next alluded to certain forms of inflammatory disease not present at birth, and in most cases not

commencing until a considerable period after it, but concerning which the general facts suggest that they must be due to some inborn peculiarity of the structure implicated. Lastly, I adverted to examples of complicated or secondary idiosyncrasy in which the individual peculiarity is not displayed immediately on the application of its exciting cause, but waits as it were for the co-operation of other influences. We found one of our best illustrations of this in the chronic poison denoted chiefly by amblyopia to which heavy smokers are in exceptional instances liable. I concluded my lecture by a brief allusion to idiosyncrasies in reference to arsenic, and was obliged by want of time to defer till to-day what I have to bring before you on the important subject of the iodides and similar salts. I shall be obliged to omit altogether what I had prepared in reference to belladonna, opium, and certain other drugs, an omission which I shall regret the less because, as just said, I am seeking only for illustrations of law and of these perhaps we shall have enough. The iodides and bromides offer us, indeed, such excellent and various illustrations of the laws of idiosyncrasy that I am almost tempted to wish that I had excluded all others and thus secured more time for the consideration of them. The modes in which these salts can produce disagreement are exceedingly varied, and concern very different parts of the system, whilst many of them are displayed by the skin in a manner which permits of their easy identification and examination. Not even the syphilitic virus itself is capable of producing such a multiplicity of pathological changes in the integument. Now it is a hæmorrhage, now a thrombosis, now an erythema, now a bulla; the commonest of all forms is an acne, but in addition to it and those which I have named we may have pustules, button-like tubercles, and in aggravated cases enormous soft tuberosous growths. If time had permitted me I should have taken occasion to advert also to a topic of much importance to us in operative practice, and should have suggested that in a considerable number of the accidents with anæsthetics it is idiosyncrasy which we encounter. Many of the deaths from chloroform occur to persons apparently in perfect health, and when only small quantities have been given and with

every possible precaution. Such cases ought probably to be placed side by side with those in which individual susceptibility becomes unexpectedly revealed to us in reference to such drugs as opium, belladonna, and the like. We waste our labour when we search for proof of heart disease, or for some flaw in the apparatus, or for some want of care in the administration. The last patient in whom, under my own care, we came near to a fatal event with chloroform, was a man at Moorfields, in whose case extraction of cataract was about to be performed. He would certainly have died but for the vigorous use of artificial respiration and the nitrite of amyl. In discussing the case afterwards I was reminded by our house-surgeon that three years before, when the other eye was operated on, the same man had caused us alarm by precisely similar symptoms. The occurrence had unfortunately been forgotten. It is probable that there are persons in whom, owing to peculiarity of nerve organisation, and not in the least to anything which we can recognise as ill health, the inhalation of chloroform will always cause an extreme depression of the heart's action. In such, if the precaution of giving beforehand a dose of opium, alcohol, or ether, be omitted, there is the utmost risk of a fatal event. Probably each anæsthetic related conditions of idiosyncrasy.

I have passed over also another subject owing to want of time which has considerable surgical interest. It is the influence of inherited structural peculiarities in favouring the occurrence of lesions which at first sight suggest no suspicion of such origin. Examples we have of this in the easy occurrence of dislocation, owing to peculiarity in joint formation, and the proneness to intussusception of the bowels, owing to the cæcum ascending colon being provided with a mesentery. I have several times known the tendency to intussusception to show itself in several members of the same family, and in some of the most marked instances in which several of the children had died of it in succession the condition referred to was found at the autopsy of one of them.

I now turn to the subject of the idiosyncrasies in reference to the iodides and bromides. It seems probable that the difference in form which the inflammation of the skin assumes is dependent upon the peculiarities of the individual, for if the patient has shown a tendency to an unusual development of the iodide rash on one occasion, and the same salt be given to him on another, even after a long interval of time, it will produce exactly the same effect. This I have witnessed repeatedly. Idiosyncrasies as regards the iodide are not manifested solely by the skin, are perhaps not primary in it, and seldom confined to it. Congestions, with excessive secretion of certain tracts of mucous membrane, are of yet more frequent occurrence than are skin rashes, but they differ from the latter in that they are, in a majority of instances, only transitory. An eruption on the skin, once developed by the iodide, persists—and indeed becomes increased—so long as the drug is given; sometimes even after it has been suspended. The iodide coryza, as it is called, on the contrary, seldom lasts more than a few days; or if it becomes chronic, always subsides into a slight affair. Thus the one would appear to imply idiosyncrasy in a far less degree than the other, and this suspension is borne out by the observation that in those who suffer from any of the more serious forms of skin eruptions there are usually other evidences that the drug is producing injurious effects. The tone of the nervous system is always lowered by it, and sometimes to an alarming extent. There is, perhaps, no drug that can be mentioned respecting which variations in the degree of idiosyncrasy are so great. I have repeatedly known doses of only half a grain produce, in the course of a couple of days, definite symptoms of poisoning; and, on the other hand, I have known a patient swallow an ounce and a-half a day of the best Apothecaries' Hall iodide for a week together without any special effect, except a feeling of lassitude and a want of tone. It is also very remarkable how, in a large majority of cases in which definite and peculiar susceptibility is at first

manifested, tolerance may subsequently be attained, and doses of ten, twenty, thirty times the amount given without obvious effect. Probably there is no drug respecting which the assertion can be more easily demonstrated, that it is not the dose, but its effect, which we should regard. It by no means follows that because a patient has an idiosyncrasy against some drug or article of diet, that we ought wholly to abstain from its use. Rather this susceptibility, in the majority of cases, proves that in him minute doses will effect the cure first as efficiently as larger ones in others. I have repeatedly cured tertiary ulcerations of the throat and skin in patients in whom I was assured iodide was a poison in all doses by giving it in quantities of half, or even a third, of a grain. In the year 1862 Mons. Bazin, of Paris, an excellent specialist, and at the same time an excellent physician, described a new disease under the name of hydroa. Of this malady he recognised several varieties, one like varicella, one resembling small-pox. On reading M. Bazin's description I was at once struck by the closeness with which they applied to several cases which had been under my own care, and in 1870 I wrote in the *British Medical Journal* a report on "hydroa," quoting M. Bazin's description, and recording my own cases together with others supplied to me by my friends. I had previously been to Paris and seen M. Bazin's models. At the time neither of us had any idea of the usual cause of the eruption, nor, I believe, had any of our readers or critics. One of the latter suggested that we had not named it correctly, and that it was only urticaria bullosa, but in doing this he gave us no clue to its cause. At this date we all knew of the acne which so commonly results from the iodide, but were not aware that this salt could in connection with idiosyncrasy produce other symptoms so much more formidable. In the session of 1869 Dr. Cholmondeley brought before the Clinical Society an example of a remarkable confluent eruption produced by the bromide; several papers had also appeared in Paris on the subject, and subsequently I convinced myself that the disease to which we had given a new name was really the bullous form of the iodide eruption. From that time to this I had seen but very few examples of "hydroa" except as the consequence of iodides or bromides. It will be seen that we had made no error in observation, but had simply described and named a disease which was new to us, and new to medical literature, but of which at the time we had not discovered the cause. When the cause was found the name became of little importance. As already hinted, however, we have by no means in mentioning the iodide acne, the iodide "hydroa," concluded the list of symptoms due to this drug. Respecting a case which I have to mention in the next group, I shall not be surprised if many remain still in doubt as to whether it ought to be placed in this position. A man came to me at the London Hospital covered with huge soft tumours, some of them as big as a child's fist. They occurred chiefly in his face, chest, and limbs. That I may avoid a lengthy description, I will simply refer you to the sketch on the wall, which is a rough copy from an excellent drawing which I now display. It will be enough to say that the moment I saw it I believed it to be an iodide eruption, and that my diagnosis was based upon the recollection of other cases unquestionably due to that cause which I had previously seen. The man had just been discharged from another hospital, and on inquiry I found that during his month's stay in it he had been steadily taking the iodide in increasing doses the whole time. The eruption was not present in the least before the drug was begun. The patient died within a fortnight of his admission under my care from exhaustion, apparently due to the extent of surface implicated. The *post-mortem* revealed nothing which threw further light upon the cause of his malady. It seemed probable that he had never had syphilis. He had gone into the hospital on account of another complaint, and when the eruption appeared it was considered to be syphilitic, and instead of suspending the remedy, its dose was increased. The dose was never more than fifteen grains three times a day. To those who

are still inclined to doubt whether this terrible eruption was really due to the iodide, I admit I have no right to be surprised if the number comprises all my audience. I would put the question, What else could it be? The microscope showed in the tubers only the results of common inflammation, and there was nothing in the least suggestive of malignancy. Above all, I would ask that a careful comparison be made with the other drawings which I have placed by its side. It will be seen that the two closely resemble each, and differ only in the greater severity in the case I have just described. In the essential features of the eruption they are exactly alike. Now there is not the slightest question as to the cause of the eruption in No. 2. It was produced by the bromide of potassium, and it occurred in connection with the drug twice to the same child. I may here remark that I know of no difference between the eruption due to iodides and those due to bromides. The same variety occurs, I think, in both, and the general laws as to idiosyncrasy are the same. The iodide, however, depresses the system far more than the bromide. The eruptions produced by bromides are, I think, attended by less constitutional disturbance, even when locally very severe, than are those due to iodides. A case well illustrating this came under my notice a few weeks ago. I was asked by a medical friend to see an infant in whose case the diagnosis had been varicella, and next small-pox; complete isolation had been enforced, but as the eruption had steadily got worse, and the child now at the end of a month remained perfectly well, all had become convinced that there was a mistake in diagnosis. I have mentioned the names which had been given to the eruption as the best means of suggesting the appearance it at first assumed, and I may add that the surgeon who attended the case was an experienced and sagacious man. The infant, when I saw it, was fat and smiling, but with its face and all four extremities absolutely covered with large buttons of most formidable appearance. Many of them had scabs, but none of them had ulcerated much. At first I was told that the eruption was present before a medical man was consulted, and before any medicine had been given, but on pressing for accurate dates, I found that my suspicion was correct, and that the surgeon was first consulted for a slight feverish cold, for which he prescribed small doses of bromide of potassium, and that the rash did not begin to appear till three days later. No suspicion having been entertained, the bromide had been continued until the day of my visit. My friend told me that he was very fond of the bromide for children, and had given it in thousands of cases, but had never before seen any eruption produced. In looking back on the experience of former years, I recollect several cases under my own care, and that of other surgeons, in whom I think there is great reason to suspect that persistence in the iodide caused death. They were cases in which an eruption which was probably due to it alone was mistaken for a specific one, and the drug pushed still further. In the report which I published in the Clinical Society's "Transactions" I have published two cases in which our eyes were opened only just in time. They were all cases in which the salt had been continued for some weeks. It may be possible, however, for fatal poisoning to occur in connection with the first few doses. In the case of a man admitted into the London Hospital some years ago, only two or three doses had been taken, and an eruption which looked like hæmorrhagic variola had been produced, together with such an amount of swelling about the neck and throat that nothing but the prompt performance of tracheotomy could have averted immediate death. The facts respecting this case were published by my colleague Dr. Stephen Mackenzie, and the same indefatigable observer has placed upon record the most extraordinary example of iodide poisoning with which I am acquainted. In this instance an infant, at 5 months, died of iodic purpura after a single dose—two grains and a-half.

(To be continued.)

Original Communications.

UNIVERSALLY CONTRACTED PELVIS, DETERMINATION OF, BY EXTERNAL MEASUREMENT.

By Prof. C. BRAUN VON FERNWALD.

Abstracted and Translated from the *Wien. Med. Zeitung*.

By Dr. J. E. BURTON,

Physician-Accoucheur to the Lying-In Hospital, Liverpool.

It is sometimes important to determine whether a particular pelvis is contracted without having recourse to a vaginal examination. In such a case external measurements may be taken, and from these conclusions drawn as to the internal capacity of the pelvis. This method originally introduced by Bugeau, was demonstrated recently by Prof. Braun on a woman in labour. The first step was to take the girth by a measuring tape, the point chosen being the symphysis and the spinous process of the last lumbar vertebra. The circumference of the pelvis at this point was 75 ctm. (29½ inches). The average circumference of the normal female pelvis, according to Stein, is 90 ctm. (35½ inches), and the conjugate diameter, 11 ctm. (4 3-16th inches). According to observation, a diminution of 5 ctm. from the normal pelvis measurement corresponds to a decrease of 1 ctm. in the conjugate. Thus, if the circumference is—

90 ctm. the conjugate will be 11 ctm.

85 " " " 10 "

80 " " " 9 "

75 " " " 8 "

Or in English measurements, if the girth at the above point is—

35½ inches, the conjugate will be 4 3-16th inches.

33½ " " " 3 14-16th "

31½ " " " 3½ "

29½ " " " 3 2-16th "

Roughly speaking, it may be said that a diminution of 2 inches from the normal girth will correspond to a shortening of the conjugate to the extent of 1-3rd inch. Thus, a girth of

35 inches will correspond to conjugate 4½ inches.

33 " " " 4 "

31 " " " 3½ "

29 " " " 3½ "

Minor differences in circumference will not be of much importance; but, on the other hand, a slight bony structure, with excess of the panniculus adiposus may influence the result. In order to test the accuracy of the method, the conjugate was shown by actual measurement to be 8½ ctm., 3 5-16th inches. The other measurements showed it to be contracted in all its dimensions, in fact, a universally contracted pelvis.

THE CHINESE MATERIA MEDICA.

By FREDERICK NEWCOME, F.S.S.

(Continued from page 548, last vol.)

CHITZU.—The berries of a species of barberry tree (*Berberis lycium*), largely grown in the province of Szechwan, and other parts of China. For these berries there is always a constant demand at reasonable prices—30 to 70 taels a picul, according to quality—on behalf of the Cantonese, the natives there fully appreciating their many perfections and putting them to an innumerable variety of purposes. Several kinds of barberry are to be found in China, all of which seem medicinally useful. The Chinese make little use of the bark except for dyeing silk and cotton goods.

YOHUA (*Carthamus tinctorius*).—This greatly esteemed remedy is neither more nor less than our ancient friend the safflower blossom of the dyer, in another form. For

medicinal purposes only such blossoms are picked as have arrived at a state of maturity, whereas those intended for the dye-market are plucked before they have completely unfolded. As the properties of this drug are so well understood any lengthy reference would be supererogatory. It once held a certain reputation here, but like many another fancy has practically had its day. On the contrary, its fashion is daily extending in China. Warm infusions are there deemed safe diaphoretics, and in a like form it is frequently taken to promote the menstrual discharge—an ancient practice in this country. It is also used in a variety of other ways. In certain districts the seeds are occasionally swallowed as a purgative, but even the "wicked Kitats," as the Tartars call them, seemingly distrust their effect. While upon the safflower question it may not be quite amiss to make a digression and say a few words anent its services as a dye. In this field its sphere of utility seems practically limitless. The better quality flowers coming from Szechwan are valued in Hankow at sixpence a pound. These are employed by the Chinese in colouring silks and satins, whereas the commoner kinds grown in Honan are reserved for cotton and paper fabrics only. It is the former dye which frequently imparts its delicate tints to the ground work and figures of the pretty silk fans now-a-days so common in shop windows. In one especial district the native dyers have apparently acquired the almost impossible art of fixing this fugitive colour so as to resist for a long while the action of both sun and atmosphere.

Somewhat curiously, medicinal safflower is only received from the Honan district, where it is commercially worth fifty per cent. less than the commonest dyeing article. This striking difference in price, added to the fact that the matured blossoms are alone bought by druggists, leads one to conjecture that only such as are found by growers to be unserviceable in dyeing are converted to medicinal uses; unless, which is quite possible, the flowers inherit more active properties through lengthened exposure to the sun's action. Upon this point it is well-nigh impossible to obtain a reliable opinion; only regular experiments, scientifically conducted, are at all likely to solve the riddle. The Chinese, it is certain, place little faith in infusions made from young buds, such as are pressed into the square cakes used by dyers. If we mistake not, it is this safflower which is sold here, not the well-matured blossoms used by native doctors. Without venturing an opinion either way, it may not be out of place to suggest that this may have something to do with the low opinion in which safflower is now held among Europeans. Anyway, it would be interesting to learn for certain why in China the buds are used for dyeing and the full-grown flowers as medicine. Needless to add the manufacture of rouge from safflower buds is carried on to a very large extent throughout the Empire.

CH'UANFU consists of the roots of the plant (*Aconitum variegatum*). These tubers are generally dark brown in colour, two inches in diameter, and resemble in shape the common English turnip. When divided longitudinally they present an ashy gray, greasy appearance, with an odd-looking irregular star in the centre. For market the roots are salted, dried, and then cut into thin strips. This medicine is distinguished by several names according to its age,—that which is four years old is called Tienh'siung, that which is three, Loufu, while that which is two years old is known as Futzi. However, the commercial value does not seem to be much affected by these distinctions, about the same price being obtained for one and all. It is said to be employed by the Chinese as a stimulant in very small doses. T'sao Wu is another drug derived from Monkshood, but from what variety is not apparently ascertained.

PATOU (*Croton Tiglium*).—About the only feature worth noting with regard to this drug is the peculiar method of administering it adopted in China. The

seeds, and not the expressed oil are given as a drastic cathartic. The croton oil plant grows in many provinces, but only seems to be cultivated regularly for the purpose in that of Szechwan.

HUAISHAN (*Dioscorea sativa*).—This medicine, which, as mentioned previously is commonly mixed with Ch'uantung (*Ophopogon Japonicus*), consists of the long tuberous roots of a species of yam, cultivated on a large scale in the province of Shensi. The roots run about six inches long by two in circumference, and when peeled have a perfectly smooth white surface and interior. They are without smell or taste, and when dried, very brittle. Huaishan is reckoned an admirable tonic and stimulant.

The inexorable laws of space and limit preclude a separate notice being given of each leading "physic," and henceforth we must content ourselves with a running fire of commentary on a few among the next most important. One somewhat mysterious medicine, Matouling, holds a high reputation for its direct action in pulmonary diseases. It is a native of Szechwan, apparently, and we further observe that it figures among the exports from Ningpo and elsewhere. Above and beyond this, and that its reputation is good, very little is known about it. Dr. Porter Smith's work does not mention it, neither has its botanical name been defined. Much the same remark applies to Tienchi, another drug, which, according to Mr. Walter Lay, Commissioner of Foreign Customs at Tamsui, in the island of Formosa, is held in deep veneration by the Chinese soldiers there "on account of the valuable properties attributed to it." What they are we know not. Here, again, all is darkness respecting the scientific name of the plant whence the drug is derived. Indeed, this state of nebulousity involves the whole question of Chinese pharmacopoeia. Botanical names have from time to time been given to most all the Chinese sanatives, but, unhappily, scientists are not quite agreed in their opinions. Dr. Bretschneider disagrees with Dr. Porter Smith, *et instar omnium*. In giving, then, the scientific name of any herb as the origin of a specific drug, it must be clearly understood to be given subject to some reservation. No end of Chinese plants are yet without name. Of these, many are unquestionably medicative, and although unrecognized, certainly find their way to the ports where they get classed among better known drugs. Moreover, Chinese plants vary materially from their European, American, or African types. In classing them, botanists are apt to go astray, especially when they have only a dried root from which to form conclusions. But be this as it may, let the names we know them by be right or wrong, there can be no gainsaying one fact, namely, that the soil of Central and Northern China is essentially suitable to the development of the active principles possessed by different herbs. Exemplary of this law we have the tea plant, rhubarb, and ginseng, all grown to most perfection there. Consequently it is unwise to assume that any one specimen of the vegetable kingdom is worthless to science, just because species of the same plant with which botanists are familiar elsewhere have been proved of negative value.

(To be continued.)

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Wolverhampton 9; Huddersfield, 12; Sunderland, Brighton, Norwich 13; Leeds 15; Birmingham, Bristol, Portsmouth, Blackburn, Plymouth, Leicester 16; London, Birkenhead 17; Sheffield, Nottingham, Cardiff 18; Edinburgh, Newcastle-on-Tyne, Derby, Bradford 19; Dublin, Halifax, Hull 20; Oldham, Salford 21; Liverpool 22; Glasgow, Bolton 23; Manchester 24; and Preston 25.

Clinical Records.

THE MIDDLESEX HOSPITAL.

Tetanus with Facial Paralysis.

Under the care of Mr. HULKE, F.R.S.

[For the report of this case we are indebted to Mr. W. ROGER WILLIAMS, F.R.C.S., Surgical Registrar.]

THE patient, a single man, æt. 27, a carpenter by trade, was admitted into the Middlesex Hospital on the morning of March 30th, 1882, with the following history:—On the previous evening he had a "stiff neck," and the following morning a "weakness" of the right side of the face. On account of the latter he walked to the hospital, not feeling very well; it was then noticed that he had right facial paralysis, together with inability to open the mouth sufficiently wide to protrude the tongue, though he could separate the teeth for nearly half an inch. Axillary temperature 100·4° F. On the back of the first phalanx of the left index finger a small pustular sore was noticed, about the size of a pea, and near it several scabbed scratches. These, he said, resulted from the graze of a saw seven days previously. Over the middle of the bridge of his nose there was a sore about the size of a sixpence, the edges of which were red and angry-looking. He said it resulted from a fall five days before admission. No enlarged glands or inflamed lymphatics could be detected in the vicinity of either of these wounds. E. T. 99°. P. 78.

The next morning the following note was made as to the patient's condition:—

He is a well-formed, well-nourished, healthy-looking man of about middle height, of dark complexion and hair, his face florid and of an icteric tint. He generally lies quietly on his back with the eyes closed, indifferent to what is going on around, except when roused, as by a loud noise, &c. Occasionally he has convulsive attacks, which seem to arise in connection with fits of dyspnoea, brought on by violent unsuccessful attempts to cough. At these times he puts his hands to his throat; the trunk and limbs are convulsively moved, and the posture rapidly changed, as if seeking relief; the face being congested. The right side of the face is completely paralysed; on the left side there is a well-marked *risus sardonicus*. Both pupils are small, equal, and active. Sclerotics are white and not jaundiced. The conjunctival blood-vessels are normal. There is no impairment of audition on either side. When spoken to he answers rationally, being quite clear in his mind, though speech is defective, because he cannot open his mouth.

The teeth are firmly clenched together, but by making an effort they can be separated for a small extent. The masseter muscles, however, are not obviously contracted, and they do not feel rigid. The muscles at the back of the neck are firmly contracted, so that he has a stiff neck, only limited lateral movements being possible.

He complains of pain in the throat and over the sternum, also of difficulty in breathing; but the sight of water does not induce excitement or convulsive attacks, and he is quite sure he has never been bitten by a dog. He is able to swallow fluids. His habits have been rather intemperate. No signs of syphilis.

P. 64, rather hard. R. 24, quiet shallow, chiefly abdominal. T. 103°. skin moist, warm. Tongue cannot be protruded, no sordes.

This afternoon, after a consultation of the physicians and surgeons of the hospital, he was transferred to the care of the former, who regarded the case as one of cerebro-spinal meningitis.

In the course of the next 24 hours the respiratory embarrassment increased, and he died the following evening with symptoms of asphyxia. Shortly before death the temperature reached 105°.

He was treated with morphia, bromide of potassium, chloral hydrate, hypodermic injection of extract of physostigma, and ice-bag to neck and head, but none of these remedies afforded much relief.

The autopsy was made 14 hours after death, by Dr. Fowler, whose notes I have followed. The weather was fine: *rigor mortis* was well-marked. The face retained the same expression it had during life—the right side placid, the left drawn, and with a *risus sardonicus*. The head and the upper part of the trunk were livid, especially posteriorly. There was a little frothy mucus about the nostrils and lips. The teeth were clenched. The body was well nourished and muscular.

The cerebral meninges were normal. The vessels over the

convexity of the brain in the occipital region were unduly full. At the base there was a little excess of sub-arachnoid fluid, but no sign of inflammation. The lateral ventricles were rather full of fluid. Otherwise the brain was normal. No fracture of the cranial bones could be detected; the temporal bones were carefully examined. The medulla and the spinal cord appeared normal; no signs of any meningitis, &c. Pleuræ normal. Bronchi contained frothy mucus. Both lungs intensely congested; recent hæmorrhagic extravasation into both lower lobes.

Right side of heart distended with dark, partially-clotted blood; left contained some post-mortem clots, but not much blood. Valves normal and competent. Muscular substance healthy. Spleen, liver, and kidneys congested. The muscular tissues throughout the body of an unusually deep reddish colour. No additional lesion could be detected in the vicinity of either of the small wounds noticed during life.

Facial paralysis as a complication of tetanus is such an exceedingly rare event, that it is not even alluded to by most authors. Dr. Ross, in vol. ii. of his "Treatise on Diseases of the Nervous System," p. 847, says:—"Motor paralysis is a rare symptom of tetanus. Rose observed paralysis of the muscles of one side of the face in a case in which the primary lesion was in the area of distribution of the facial nerve."

Whether the latter condition held in this case is doubtful, since there was a prior wound on the finger, the case illustrates the importance of recognising the occasional association of facial paralysis with tetanus.

As pointed out by Mr. Hulke, other noteworthy points in connection with it are:—The complete absence of tetanic contraction of the muscles of the trunk and limbs; the clonic character of the spasms of these parts; the complete absence from them of motor disorder during the intervals; and the ability of the man to execute complex purposive movements.

The Mineral Waters of Europe.

THE "MEDICAL PRESS"

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.
President of the Pharmaceutical Society of Ireland, Lecturer on Chemistry, Carmichael College of Medicine, &c.

WITH

NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.
Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 551, last vol.)

THERAPEUTICS OF CHALYBEATE WATERS.

A MORE moderate estimate is now entertained than that which formerly prevailed concerning the value of chalybeate waters. This change of opinion may be partly due to the reaction which naturally follows exaggerated views, but is probably still more to be attributed to the progress of chemistry having placed at our disposal so many ferruginous preparations. Moreover, careful study of the therapeutics of iron has led to greater discrimination in its use. The best effects of the metal can usually be obtained from appropriate pharmaceutical preparations, but we need not, therefore, overlook the benefits which so often accrue from the complete change involved in a visit to one of the many agreeable spas. Many cases of poverty of blood are easily cured by diet, fresh air, exercise, and other influences which promote nutrition. The healthy system can extract sufficient iron from a suitable diet. On the other hand, there are many cases in which the deficiency of this constituent of the body is best directly supplied by the presentation of the metal to the stomach in a suitable form.

Generally speaking, the more acute and direct the anæmia, the more rapidly will the iron be assimilated. As a necessary constituent of the body, the metal may be regarded as a food. Its deficiency is at once shown in a change in the blood, the corpuscles of which are rapidly replaced under its influence. Its hæmatinic effect can therefore be determined in any given cases by counting the corpuscles. But for this purpose only small doses are required, and should be given in the most easily assimilable form. It has been estimated that in health a grain per day is usually taken up and removed, but in some chlorotics that four or five times as much has been for a short time assimilated. Further estimates have been formed of the total deficiency of iron that may take place in disease and be restored by treatment. According to these calculations, the deficiency never exceeds 15 or 20 grains; from 37 to 47 grains are present in the blood of a healthy adult. The blood will not take up more iron nor form more hæmatin than the normal amount, so that we cannot increase the richness of the blood beyond the standard of health. But it does not follow that unlimited quantities may be given. On the contrary, large doses are likely to derange the digestive organs, and thus defeat the object with which they are given. They impede the secretions, and thereby hinder absorption and constipate the bowels. Something, of course, depends on the form in which the iron is presented, the preparation, and the degree of dilution; something, too, on the state of the stomach. The presence of carbonic acid is also a point not to be overlooked, and we have already discussed the effects of this gas. The unabsorbed portion of the dose passes away in the fæces, chiefly as a sulphide, and is the cause of the blackening of the evacuations. Small quantities of sulphide constipate by checking the secretion of the intestinal mucous membrane, but larger quantities may act as an irritant, and so produce diarrhoea.

After absorption iron is eliminated by the kidneys, skin, and liver. It chiefly passes into the urine, and the rate at which this occurs seems to accord with the rate of absorption, the amount excreted increasing with the smallness of the dose taken.

Somewhat contradictory results have been reported as to the effect iron has on the pulse. It is reported generally to give tone to the circulation and to make the pulse slower. Others, however, state that it increases the frequency of the pulse, and it is a common observation that it appears to increase congestions. The effects of iron waters, which contain carbonic acid, ought not to be brought forward to elucidate this question, as the gas itself would manifestly affect the result. As the iron favours oxidation, it may be assumed that this tends to increase the production of heat and to quicken the pulse, but this last symptom may be more than neutralised at a later stage by the increased strength which follows improved sanguification. Iron would seem to give tone to the capillaries and even to stimulate their contraction, to which effect may be partly ascribed its power over hæmorrhages and discharges.

If the final use of iron in the system cannot be completely traced, we may certainly conclude that it is necessary to the formation of the blood globules, and when deficient should be supplied in the lightest form. The small quantity present in chalybeate waters is suffi-

cient to produce the therapeutical effects just as in the cases of other preparations. Small doses, as already stated, are most efficient. In the mineral waters carbonic acid is a frequent constituent, and this will often stimulate the stomach and prove an excellent digestive. When too abundant a portion may be allowed to escape, and, indeed, when the bottled waters are used they may often be safely warmed, and will then be more grateful to delicate stomachs for, as previously shown, large quantities of gas are often injurious. In most of these waters the iron exists as a carbonate of the protoxide. Those which contain the sulphate are much heavier, and disagreeable to the palate. They are, however, occasionally useful.

Some of the weakest chalybeate waters have been spoken of in our account of table waters. We have now to enumerate those of which an analysis has been given in our last report.

Roisdorf contains only a small amount of solid ingredients. The proportion of iron gives it a distinct value as a mild, uncomplicated, chalybeate water.

Homburgh is more frequented for its salt springs, while its position makes it a favourite resort. Nevertheless, it boasts its iron spring, with which the other treatment may be combined or supplemented. We do not frequently employ the bottled waters.

Spa, the name of which has become generic, is an agreeable and easily accessible resort, where the chalybeate waters can be supplemented by luxurious bathing, horse exercise, and other agreeable circumstances. The town is situated 1,000 feet above the sea level, in one of the valleys of the Ardennes, and is a pleasant, bracing, but mild resort. The bottled waters seem to be rather weaker than those of the principal spring—the *Pouhon*, but they are of the same character.

Wiesbaden, so famous for gout, is generally classed with salt waters, the proportion of chloride of sodium being large. It also contains chloride of ammonium—as much as 5·7 grs. per half-pint. The saline ingredients are 33·6 grs. out of a total of 45·4, and the iron is only 0·3. It also contains arsenic. Only one of the seventeen wells is used for drinking, the fame of Wiesbaden depending on its thermal baths.

Harrogate, so renowned for its sulphur waters, has also a remarkable iron spring, in which the metal is found as a chloride. This well is a most valuable addition to the other springs of this celebrated English resort, the bracing climate of which is more tonic than that of many Continental Spas. There are other constituents of this water which add to its value, and give it a position quite unique.

Royal is often classed with Ems, for which it is a very good substitute, while its climate is better, for being 1,380 feet above the sea (Ems is only 291), the heat in July and August is not so great nor so oppressive as at Ems. It is a mild alkaline chalybeate water, and is recommended in mucous catarrhs, and dyspepsia attended with anæmia.

Pyrmont, once the leading chalybeate Spa, still offers sufficient attractions to make a sojourn pleasant, while its waters have for centuries held a high place among chalybeates. They are highly charged with carbonic acid, and the stimulating effect of this is compared by some

enthusiasts to that of champagne. The water is agreeable to the taste. The iron is here associated with calcareous salts.

Shelfanger, a mild alkaline chalybeate, in which the iron is associated with magnesia, does not seem to constipate, and is of agreeable flavour.

GENERAL MEDICAL COUNCIL.

SIXTH DAY, MONDAY, JULY 3.

VIVA VOCE EXAMINATIONS.

DISCUSSION was resumed on the Visitors' suggestion that candidates who failed to pass the written part of an examination should be precluded from proceeding to the *viva voce* test.

Mr. MARSHALL considered such a regulation would act unfairly on many candidates. Although at the present time anyone getting less than three out of ten marks was unable to make up the lost ground at the primary examination of the Royal College of Surgeons, still he did not think that the few who thus failed should be stayed from proceeding to the oral test.

Mr. MACNAMARA, in seconding the motion, urged that it was futile to continue the examination of candidates hopelessly rejected at an early period. He thought it very desirable that written examinations should be held at local centres, the then answers forwarded to the examiners at the general centre, by whom they would be carefully considered, and all candidates who had failed irretrievably in this first stage should be informed of their position, and thus saved the expense and annoyance of subsequent rejection. Even if the Council did not endorse the Visitors' conclusion then, he was sure it would at a future time.

Dr. WARREN thought it a great hardship that candidates who fail in a single subject should be compelled to go through the whole test again. He wished the Council could see its way to recommend that examining bodies should consider the advisability of not requiring the whole area of the examination to be gone over again. Non-qualified assistants would accept such a change as highly advantageous to them. He thought it would be advantageous if some such instructions as the following were added: "And that where a candidate has been referred in his written and oral examination only because he has not obtained pass marks in one or more, but not in all, the subjects, when he again comes up to examination he should not be examined in those subjects in which he had obtained satisfactory marks; and that any candidate who has once been referred may take any of the subjects in detail, and should not be obliged to present himself for all the subjects included in that examination."

Mr. SIMON desired to register a *caveat* as to many of Dr. Watson's conclusions. The system advised would meet with his strong dissent. He was inclined to vote for the motion, but would hesitate to do so in the face of objections from the Royal College of Surgeons. The economy of time resulting from the adoption of the motion might be considerable.

Dr. HUMPHRY thought the mode of conducting their own examinations should be left entirely to the Boards. There was danger that if candidates were admitted to a "stages" examination, the tests would become too meagre. There were objections to stopping candidates who fail to pass the written part of an examination. Such men would be prevented from obtaining that experience of examination which was of material assistance to them in their further preparation. He was sure the real cause of the high number of rejections was consequent on their inability to accomplish all required of them in the time given.

Dr. QUAIN said the influence of the Council was exerted formerly by framing general recommendations. It ought not to interfere with the minute arrangements of the bodies.

Mr. MARSHALL admitted there would be economy of time often in adopting the proposal, but to so small an extent that it was unworthy of consideration. The examiners did not desire to economise in that way, and they had other reasons also against the scheme. It was better for a man to pass through the whole examination, whatever his certainty of

rejection. Mr. MARSHALL maintained that the experience of the oral was of high service to candidates. He was certain the splitting of the examination into segments, permitting candidates to pass bit by bit, would lead to the greatest abuses. He agreed with Dr. QUAIN.

Rev. Dr. HAUGHTON thought the Council might be glad to hear the views of the Universities on the question under discussion. No one in Dublin University could understand Conclusion 11 of the Visitors; that was due to there being no oral examination as such, but *practical* examinations in dissecting-rooms, wards, and laboratories. This examination was ten times as important as the written answer to papers of questions. It was wrong to permit candidates to pass any examination bit by bit. The *morale* of the motion of Mr. Teale was questionable, and he would oppose it.

Mr. MACNAMARA wished Dr. Haughton to explain how he could oppose piece-meal examination when at Dublin University candidates passed the subjects in groups.

Dr. SCOTT ORR agreed that candidates who were rejected at examinations obtained valuable experience while undergoing the test. Moreover, justice to candidates demanded they should be allowed to go through it all.

Dr. HALDANE and Sir Wm. GULL opposed the motion.

Mr. TEALE considered that, although opposed to the spirit of the Council, Dr. Watson's suggestions deserved consideration. The conclusions were not put forth as recommendations, but they simply enabled discussion of the Visitors' report to be more readily entered on.

The motion being about to be put to the vote, Sir Wm. Gull moved, and Mr. Simon seconded, the "previous question," which was negatived, and the original motion being put, was lost.

ADDITIONAL SUBJECTS OF EXAMINATION.

Mr. TEALE then moved the conclusion of the Visitors, that, "In any future revision of the curriculum the subjects of hygiene, ophthalmology, and mental disease should have serious consideration—and perhaps admission—under careful limitation, as distinct elements of examination." In support of this Mr. Teale urged the necessity of every surgeon being able to treat common eye diseases, and that he should have a bird's eye view of special subjects. Prof. Swanzy recommended that students should be specially examined in ophthalmology.

Dr. BANKS urged that no part of a general practitioner's duty was more important than that of deciding on the mental state of patients. Two years previously the same question was considered by the Council and shelved. He was convinced of the absolute necessity that mental disease should form part of every examination for qualifications to practise. Three months' attendance at an asylum ought to be required. He would second the motion.

Mr. TURNER expressed surprise at the appearance of such a resolution. He could conceive no adequate curriculum from which the subjects named were absent; and since it was certain that the subjects were part of regular study, it was unnecessary to pass such a resolution.

Dr. STORRER said the University of London always regarded mental diseases as part of the subject of medicine, but feeling the impossibility of making any special regulation on it, had made three months' attendance at an asylum alternative with other clinical work, and further advised candidates for the M.B. to make themselves particularly acquainted with the clinical aspect of insanity. He thought, however, it would be unwise to frame a recommendation to the licensing bodies on this subject.

Sir Wm. GULL agreed that it was undesirable to split up study too much.

Rev. Dr. HAUGHTON said that the five examining bodies in Ireland did not examine on the subject of insanity. Any questions bearing on it were vague ones on the law, &c., and did not in any way benefit the public.

Mr. MACNAMARA opposed the motion.

The motion was lost.

HYGIENE.

Mr. MACNAMARA moved that the Committee should note with approval the conclusion arrived at by the Visitors in respect to the importance of hygiene as a subject of examination. The Royal College of Surgeons of Ireland appointed a Professor of Hygiene, but had not yet established examination in it. A knowledge of hygiene, however, was of great value and high importance to every practitioner.

Mr. COLLINS seconded the motion.

Mr. SIMON moved, and Mr. TEALE seconded, "That, considering how important it is to all medical practitioners to possess a competent knowledge of hygiene and preventive medicine, the Council takes note of the suggestion of Dr. Gairdner and Mr. Stokes that these subjects ought to form a more independent part than they do of the examinations of all corporations."

Mr. TEALE explained that he did not agree with the suggestion of Dr. Gairdner and Mr. Stokes in regard to making hygiene and preventive medicine compulsory subjects of examination.

Dr. PETTIGREW considered that the period of study spent by students of medicine did not permit the addition of fresh subjects to the curriculum. The matter would have to be discussed ere long in connection with revision of the curriculum.

Dr. LYONS took objection to the term "preventive medicine," which he contended was a loose term, meaningless, and unworthy of being employed by so august a body as the Medical Council.

Mr. SIMON pointed out that the term had been used by the Visitors, and this was a sufficient reason for retaining it. He was surprised at the objection raised to the use of the term, and could not understand Dr. Lyons' onslaught.

Rev. Dr. HAUGHTON regretted the Council should waste its time in useless discussion. He would not accept either of the proposals before the Council; the differing opinions as to the meaning of the terms employed explained the diversity of conclusions expressed by members of the Council. The Dublin University estimate of "State medicine" included a knowledge of law, pathology, medicine, meteorology, engineering, chemistry, &c., &c. No candidate could enter for it unless previously a Bachelor of Medicine or Surgery at Oxford, Cambridge, or Dublin. It was, therefore, impossible to defraud the public by endorsing a less inclusive description of hygiene.

On a division Mr. Simon's amendment was carried. It was then put as a substantive motion and carried.

This concluded the consideration of the Visitors' Report, and the Council at once resumed.

UNQUALIFIED ASSISTANTS.

The following Councilmen were appointed:—Dr. Chambers, Dr. Lyons, Mr. Macnamara, Mr. Simon, Dr. Pyle, and Dr. Watson.

VISITORS' REPORT.

Rev. Dr. HAUGHTON thought that the Council, having completed its consideration in Committee of the Visitors' Report, it was right that representatives of the corporations visited should be invited to add any remarks they wished supplementary to the Visitors' conclusions, in accordance with his own motion of June 29.

The PRESIDENT having admitted this,

Sir WM. GULL said this course would involve much waste of time. The Council had really heard already all that could be said.

After considerable further conversation on the matter,

Mr. SIMON suggested that the representatives of licensing bodies should take the opportunity of debate on the question of Prof. Haughton's motion to make any statement desirable.

Dr. AQUILA SMITH congratulated the Council on having arrived at this decision. He drew attention to the absence of specimens of answers given at examinations of the Royal College of Physicians of Ireland. In view of the strong remarks made by Mr. Teale on a preceding day respecting the deficient education of rejected candidates at many examinations, it was regrettable the Visitors had not decided to submit the answers in their possession to the Council together with the report.

Dr. HALDANE said the report did not express the Visitors' opinion of the examinations surveyed, and this, he held, nullified the value of the report, as it was of the first importance for Visitors of examinations to say in what regard they thought them capable of amendment, and in what excellent. The Visitors also had omitted to inspect the single examinations of the Colleges of Physicians and Surgeons, Edinburgh; they visited only the double qualification examination. The report also contained several errors. Examiners were elected for special knowledge, and were not, as the Visitors said, appointed to groups of subjects after election. The Visitors had committed errors in many other matters also.

Dr. WATSON, on behalf of the Royal College of Surgeons of Edinburgh, asked if the Visitors were dissatisfied with the

tests imposed by that College. The Visitors had, in fact, never visited the examination. He went at some length into a repudiation of the charges brought against the College of Surgeons.

Mr. TEALE said an answer could not be given until he had consulted his colleagues. He might explain that the reason why examination papers had not been printed was because of the very considerable difficulties in the way of selection and correction in printing such a mass of papers.

Dr. QUAIN explained that the Visitors had no right to demand the answers.

The subject then dropped.

SEVENTH DAY, TUESDAY, JULY 4.

CHARGE AGAINST A REGISTERED PRACTITIONER.

The Council was occupied during the whole sitting in the investigation of a charge of disgraceful conduct. The subject was brought under the notice of the Council in the following letter, dated June 8th, from Mr. R. H. S. Carpenter, the Secretary of the Medical Alliance Association.

"Gentlemen,—I have to apply to you to remove from the Medical Register the name of David Beatson Murdoch, for disgraceful conduct in the practice of his profession, as described upon oath during the proceedings of two inquests held by Sir John Humphreys on June 7th, a report of which, taken from the *Telegraph* of to-day's date, I herewith enclose to you. You will see the various addresses of Dr. Murdoch, ranging from Dalston to the East India Road, in the accompanying report."

The case was first investigated by the English Branch Council, and placed by them in the hands of the Registrar, to be brought before the General Council.

Mr. FARRER, the solicitor to the Council, stated that he had, in accordance with instructions, summoned Mr. Murdoch to attend the meeting. The charges against him were—1. That he had a number of "dispensaries" at which he employed unqualified assistants; 2. That he allowed unqualified persons to sign in his name false certificates of death; 3. That, in cases under the care of his unqualified assistants, he presented himself at the last moment so as to be able to sign a certificate. Mr. Farrer was of opinion, with regard to the second and third charges, that there was no evidence that it was Mr. Murdoch's habit to act in the manner stated. He (Mr. Murdoch) had stated that false certificates had been signed without his authority, and there was no evidence that he had given such authority. There was, however, proof that he had employed unqualified assistants, both in the evidence given at the coroners' inquests and in his own letters. The evidence at the inquests, which was laid before the Council, showed that two children, who had died, had been attended at a so-called "Provident Dispensary" at 149 St. Leonard's Road, by an unqualified person named Gouverneur Hamilton Griffin, calling himself also "Colonel" Griffin, acting as Mr. Murdoch's assistant.

Mr. MURDOCH had addressed to the Council a letter, of which the following are the main points:—

"I fully admit my fault in not having inquired thoroughly into the antecedents of the man who has brought upon me so much trouble—I mean Mr. G. H. Griffin. I was aware that he had assisted another medical man, and I learned that he was well spoken of by all classes of patients, many of whom stated that he cured their complaints, that *he was clever* (to use a popular expression), and they praised his kind attention and gentlemanly demeanour. I myself was misled into the belief that he was a man in whom I could repose confidence. He informed me that he had studied medicine and law in Canada, and that he possessed a Canadian diploma.

"I have been much blamed because a certificate of death with my name subscribed was handed to the parents of the deceased by Mr. Griffin. I told the coroner's officer, and also Dr. McGill, who made the post-mortem examination, that I knew nothing about the child's death, and that I had not written the certificate, which has now proved to be nothing more or less than a forgery.

"I swore before the coroner, I have since sworn in the presence of a Commissioner of Oaths, and I have confirmed my oath before a magistrate, that *I have never authorised anyone to sign a certificate of death, or to use my name for such a purpose.*

"I acknowledge my error in employing unqualified assistants, although I have never expected them to do more than treat common cases, such as coughs and colds, simple diarrhoea, &c., which many people would treat themselves without con-

sulting a medical man. I know that it is no excuse for me to say that it is a constant custom in the profession to employ unqualified men, and that I err with the multitude of my professional brethren.

"I see now the evil of such a system, and I assure you, gentlemen, I have learned a sad lesson.

"In conclusion, I ask your pardon. I promise to exercise more discretion in future, and I trust that you will have no reason to complain of my professional conduct. I shall not employ another unqualified assistant, except for subordinate duties, unless he be under the direct surveillance of a legally qualified man; and, further, I will not undertake more duties than I can fully and conscientiously perform."

Mr. MURDOCH was called in, and questioned by Mr. Farrer, and by several members of the Council through the President and Solicitor. His replies were generally in accordance with his letter.

The Council deliberated in private for more than two hours, after which Mr. Murdoch was again called in, and informed by the PRESIDENT that the Council had adjudged him, in the words of the Medical Act, to have been "guilty of an infamous conduct in a professional respect," but that they had decided not now to remove his name from the Register, he having promised to desist from the practice of which complaint had been made.

EIGHTH DAY, WEDNESDAY, JULY 5.

The minutes of the preceding day's meeting having been read,

Mr. SIMON took objection to the form in which these minutes were recorded. He doubted their accuracy as a report of the proceedings.

The PRESIDENT said this question had occurred to him when he first saw the printed minutes. The minutes had been amended, to meet the requirements of the case.

Half-an-hour having been spent in discussing the subject of revision, the Council resolved to confirm the minutes as amended to represent what actually took place.

IMPROPER QUALIFICATION.

Mr. MACNAMARA introduced the case of Mr. Dixon, which had been complained of by the Australian branch of the British Medical Association, this person having, it was asserted, obtained a medical qualification without fulfilling the necessary curriculum and passing prescribed examinations. The Australian authorities demanded to be informed on certain points, and to have an explanation of the irregularities committed by the Apothecaries' Hall in Dublin.

Mr. COLLINS explained that the Hall had power to depart from rules laid down for education, &c., in cases where it seemed desirable. Two accusations of carelessness and informality were charged against the Hall. He had carefully taken part in the deliberations on the case in question, and it had been most fully and carefully discussed. Mr. Dixon's education commenced three years before 1858; he had been unable to remain in North Europe long enough to complete a curriculum on account of delicate health. It was true he had not conformed to all the requirements laid down in respect of candidates for the licence of the Hall, but in its discretion the Hall had acted in this case, as had been done in previous cases by direction of the Government, which, in 1840, required the Hall, in pursuance of powers conferred on it by Act of Parliament, to license a number of practitioners in the North of Ireland. Several legal opinions concurred in showing that the Hall had considerable power of action to license persons whom it considered it desirable to so license in the public interest; it could, indeed, examine candidates *sine curriculo*. The Hall thought it had done rightly in admitting Mr. Dixon to examination, and, when he passed this satisfactorily, to license him. He would move that the Council, having considered the statements respecting Mr. Dixon, and the reply of the Hall thereto, should decide it to be unnecessary to act further in the matter.

Mr. MACNAMARA seconded the motion. He thought it should be said that no mercenary motives influenced the College in their action.

Rev. Dr. HAUGHTON supported the motion.

Mr. SIMON concurred, but suggested a rider should be added to indicate that future examinations *sine curriculo* should be conducted with the sanction alone of the Council or Branch Council.

The motion was carried as proposed by Mr. Collins.

THE CASE OF G. S. SYMMONS.

On the question of a petition from George S. Symmons, who had been struck off the Medical Register on account of criminal conduct and imprisonment, for restoration of his name to the Register,

Dr. PITMAN insisted that the Council had no legal power to restore names to the Register, notwithstanding that it had previously done so. He moved that opinion of counsel be taken on this subject.

Dr. CHAMBERS seconded the motion, which was carried.

THE CASE OF WM. STORY.

The case of Wm. Story, convicted of arson in October last, came under consideration in connection with a letter received from the Royal College of Surgeons of England, announcing that Mr. Story had been deprived of his Fellowship of the College.

Mr. SIMON and Mr. MACNAMARA thought a decision on the question of removing the name from the Register should be deferred till counsel's opinion on the point raised by Dr. Pitman had been obtained.

Rev. Dr. HAUGHTON moved that the name be at once removed from the Register.

Mr. MARSHALL seconded the motion.

Mr. SIMON would vote for the motion if the Council retained the option of restoring the name at the termination of the period of punishment awarded by the law. As it was he adhered to the opinion he had already uttered.

The PRESIDENT said the same doubts had been expressed by Sir James Paget.

The motion was carried, 8 voting for, and 5 against.

THE CASE OF DR. HOAR.

The evidence relating to the divorce suit in which, on June 20th last, Dr. Wm. Hoar, of Maidstone, was found guilty of adultery with one of his own patients, and cast in damages of £5,000, having been brought under the notice of the Council,

Mr. SIMON and Dr. QUAIN intimated that the case could only be considered on the ground of infamous professional conduct, and could only be tried in a regular, formal manner.

Dr. HAUGHTON moved that the case be referred for consideration by the Branch Council.

This course was followed.

VISITATION REPORT.

The Report of the Committee of the whole Council on the conclusions of the Visitors of Examinations was presented, and consisted of the following clauses:—

1. "That it is desirable that every 'primary' or 'first part' examination shall include dissections by every candidate.
2. "That in view of the great and increasing range of chemical and physiological science, it is particularly desirable, in regard to those subjects, that examining bodies should comply with the Council's Recommendation 40, and that candidates should be apprised beforehand of the limits of the examination in these subjects.
3. "That at the final examinations, candidates should be practically examined in anatomy, in its relation to practical medicine and practical surgery.
4. "That the application of bandages and splints should be required in every surgical examination.
5. "That it is desirable that in every final examination for a surgical diploma, candidates should, as far as practicable, be required to perform operations on the dead subject in accordance with the intention of the Council's Recommendation 44.
6. "That the practical examinations in chemistry should be conducted in a laboratory.
7. "That it is desirable that the recognition of microscopical specimens, normal and morbid, should form a part of the examinations for medical and surgical diplomas.
8. "That the Committee agree with the following opinion of the Visitors:—'That in oral examinations, notwithstanding any general rule which limits examinations, for instance, to ten minutes or a quarter of an hour, a margin of additional time for satisfying the Examiners in all doubtful cases should be provided.'
9. "That considering how important it is to all medical practitioners to possess a competent knowledge of hygiene and preventive medicine, the Council takes note of the suggestion of Dr. Gairdner and Mr. Stokes, that these

subjects ought to form a more independent part than they do of the examinations of all Corporations."

DENTAL BUSINESS.

The question of purifying the Dental Register, and of the opinions as to the Council's power in the matter, was opened by

Dr. QUAIN, who said the Dental Committee had been much misunderstood. Its first step had been to require from candidates for registration a schedule of their claim, and statements as to their employment, as advised by the Dental Reform Association. When the Register was published numerous communications were received from different persons and Associations. Mr. Turner, B.D.A., was to be regarded as plaintiff in the charge. This gentleman addressed a letter to all newly registered dentists not on the Chemists' Register, requesting them to demand the erasure of their names from the Dental Register, and holding out a threat of prosecution for mis-statement if they did not do so. On the other hand, registered dentists had forwarded letters in defence of their conduct, they having been astounded at the receipt of the letter referred to from Mr. Turner. This gentleman had sent a second circular, in the same terms, to all whose names were objected to by his Association. The Dental Committee, July 16, 1880, resolved that the letters and documents referred to it by the Council should be placed in counsel's hands for report and opinion thereon. The Committee subsequently considered the suggested expurgation of the Register, and found out numerous facts, which were submitted to the General Council, and inquiry at a cost of £600 was gone into. Mr. Ouvry carefully went into all the facts, and obtained other eminent opinions on them to sustain his own. The questions respecting other opinions, of Mr. Bowen, Mr. Fitzgerald, &c., were not reasonable. The Council, on Feb. 3rd, 1881, decided that no evidence was forthcoming to show that the dentists complained of were not *bona fide* engaged in dentistry at the time the Act passed, and further, that it saw no reason to direct the removal of any of the names so complained of from the Register. The British Dental Association had forwarded a communication quoting the opinion of the late Sir John Holker and Mr. Fitzgerald, on which the Executive Committee decided that it was the function of the Association, and not of the Council, to proceed to steps for the removal of a name from the Register. This being unsatisfactory to the Association, it had addressed the following letter to the Council:—

"40 Leicester Square, July 16th, 1881.

"Dear Sir,—I am requested by the Business Committee of the British Dental Association to forward to you the accompanying opinion, and to beg that you will place it before the Medical Council, together with the enclosed explanatory resolution.

"I am, dear Sir, yours very truly,

"JAMES SMITH TURNER,

"Hon. Sec. B.D.A."

The explanatory resolution is as follows:—"That in strict conformity with the practice uniformly followed of placing before the Medical Council any facts or opinions bearing upon the administration of the Dentists' Act of which the Association may have become possessed, the joint opinion of Sir John Holker, Mr. R. S. Wright, and Mr. G. A. R. Fitzgerald, upon the meaning of Section 6, Subsection (c), be at once forwarded to the Medical Council: that the Association venture to hope the Council will cause to be placed on their minutes the accompanying joint opinion, together with the high legal opinion of Mr. (now Mr. Justice) Bowen, read before the Council in July, 1880, with the opinion, also then read, of Mr. G. A. R. Fitzgerald: and that the Association earnestly hope in the presence of a great preponderance of high legal opinion in favour of a correction of the Dentists' Register, the Council will restore to the Register the recently erased descriptive terms 'with medicine,' 'pharmacy,' &c.: and at its convenience proceed to the correction of the Register by the erasure of names registered in the midst of doubt, or take such other steps as may lead to the production of a Register legally correct."

On this the Dental Committee passed the following resolution:—

Resolved:—"That the Committee acknowledge the receipt of the foregoing communication, and inform Mr. J. S. Turner that, in the opinion of the Committee, the steps requisite to be taken to try the correctness of the course taken by the General Council, under the advice laid before it, rest with the

Dental Association, and not, as suggested in the opinion now forwarded, by the removal of a name which, in the judgment of the Council, is registered in conformity with law."

Mr. TURNER explained the opinion of Mr. R. S. Wright, Sir John Holker, and Mr. Fitzgerald, which was different from that given by counsel previously applied to. He had requested the latter to reconsider their conclusions, and the result was that he had obtained a most carefully considered opinion, which he regarded as the best yet enunciated. They decided that any person engaged *bona fide* in the practice of dentistry could claim to be placed on the Register, notwithstanding they might carry on other business than that of dentistry. The Legislature, they thought, in passing the Act, desired to preserve the full previous rights of all persons practising dentistry before the Act became law. Mr. Turner strongly advised the Council to follow the advice given by the counsel appealed to by themselves, and not to pursue the action recommended by legal advisers of the opposite side.

Dr. STORRAR moved, "That the opinions of Mr. Bowen, Mr. Fitzgerald, the Solicitor-General, and Sir John Holker, in regard to the registration of dentists under the Dentists' Act (1878), be entered in the General Council's minutes." This course, he said, he urged because the Council should carefully avoid the suspicion of favouritism, and hence all their opinions should be placed on the minutes.

Dr. PYLE seconded the motion.

Mr. TURNER said he had asked last year to see Mr. Justice Bowen's opinion, and he still thought it should be brought before the Council, especially since it had been obtained by the Council for its own guidance. He thought Dr. Storrar's request a reasonable one.

Mr. MACNAMARA suggested that all the opinions were guided by the Dentists' Act, whether they preceded or followed the compilation of the Register. He thought Dr. Storrar's request worthy of support.

The PRESIDENT pointed out that the opinions were obtained for the Council itself. Every member could obtain copies and examine them at any time; but they were not intended for publication.

Mr. TURNER said it would be very unwise to make known publicly confidential opinions of counsel.

Rev. Dr. HAUGHTON asked why, if Mr. Farrer's advice was right, certain opinions had already been printed and circulated?

Dr. QUAIN said Mr. Bowen's opinion had been acted upon, and through it all the trouble experienced had arisen. He had himself privately obtained an opinion from Mr. Lumley Smith, who urged that any person combining dentistry with other calling was not ineligible for registration. He insisted that it was the duty of the Council to protect the poor who earned their bread, as well as to guard the interests of dentists with medical qualifications. He moved, as a rider to the motion, that Mr. Lumley Smith's opinion should be entered on the minutes. The Council, when it accepted one opinion, ought not to tack on to it other opinions. The dentists were themselves to blame for their anomalous position. They had no position of their own, and had acted foolishly in not obtaining powers to conduct their own affairs, in place of relegating the functions proper to their own authorities to the Council. He hoped the question might be dropped.

Dr. AQUILLA SMITH urged the necessity for caution in the matter under discussion, and that the Council should accept Mr. Turner's advice.

Sir WM. GULL opposed the motion as being impracticable. The opinions obtained by the Council should be considered confidential, and moved an amendment to that effect, which Dr. Lyons seconded.

Dr. STORRAR said the opinions obtained by the Council since its foundation had, with few exceptions, been entered on the minutes. He insisted that there was no ground to charge the Dental Association with omitting to obtain powers to govern their profession. The Council's duty was to administer the Dentists' Act, and he still considered his motion should be passed.

The PRESIDENT, after pointing out that opinions had been formerly entered on the minutes, said he had received many communications on the subject of the Dentists' Register.

The amendment was then put and carried, and, being put as a substantive motion and carried, the original motion was lost, the minority consisting of Drs. Haughton, Pyle, Scott Orr, Storrar, Mr. Turner, Mr. Macnamara, and Dr. Fergus.

Mr. TURNER then moved, in view of the discrepancies existing between the opinions received, and to save future

discussion, that the Council adopt the recommendation of the executive committee to obtain further advice on the whole subject.

NINTH DAY, THURSDAY, JULY 6.

VISITATION OF EXAMINATIONS.

Mr. TEALE moved that the above report (see above, Wednesday's proceedings) be received and entered on the minutes.

This was carried.

Mr. TEALE then moved each conclusion separately. No opposition was given to 1, 2, 3, but on 4,

Rev. Dr. HAUGHTON thought the recommendation should take the form of an injunction.

The clause was passed, as also were 5, 6, and 7.

To No. 8 Rev. Dr. HAUGHTON strongly objected. The Council was going undesirably and dangerously outside its province in going into such details. The University of Dublin would register a strong opinion adverse to the Council if such a recommendation were forwarded to it. He thought the principle of the clause a good one, but that it was unwise for the Council to descend to such details.

Dr. PETTIGREW supported the clause.

Dr. HALDANE thought Dr. Haughton's objections fairly grounded, and he would not support the clause.

Mr. MARSHALL thought it the duty of the Council to advise on the character of examinations, but not to suggest the mode of carrying them out. Such details as those dealt with in the clause were no concern of the Council. After all, the resolution, if passed, would be of doubtful effect, or of none whatever, for it was open to examiners to deny the existence of "doubtful" cases.

Prof. HUMPHRY suggested modification of the clause, and moved as an amendment, that the "Council should direct the attention of examining bodies to the 'opinion of the Visitors that,' &c.

Mr. TURNER seconded the amendment. He thought it would be a pity if the clause was lost; it had been discussed at some length by the Council, and if it went down to the bodies it might do good.

Dr. AQUILLA SMITH supported the amendment.

Dr. LYONS thought the objection of interfering with details not tenable after the recognition of such interference given in preceding clauses. He could see no difference of principle in the several cases of interference authorised by vote of the Council.

Rev. Dr. HAUGHTON thought the amendment open to greater objection than the original clause. Any communication to the examining bodies should proceed direct from the Council itself, and not from an unknown Committee.

The amendment was put and carried, and being put as a substantive motion, was carried also.

Mr. TEALE thought it unnecessary to move the acceptance of No. 9.

Mr. MACNAMARA regretted the action of Mr. Teale, especially because of the latter's disagreement with the opinion expressed in No. 9. He would move that the clause be officially brought to the attention of licensing bodies. These should be encouraged in any attempt to foster the study of hygiene.

After further discussion,

Mr. TEALE proposed, and Mr. MACNAMARA seconded, that both 8 and 9 should be recommended to the attention of the licensing bodies.

Dr. BANKS remarked on the omission of mental disease from the clause, and moved an amendment that "the subject of mental disease be drawn to the attention of the authorities."

Rev. Dr. HAUGHTON seconded the amendment.

The President pointed out that the proposal should take the form of a substantive motion, and follow after clause 9.

Clause 9 was then passed, and on Dr. Banks' addition being proposed,

Mr. SIMON deprecated emphasising any particular study.

Mr. MACNAMARA said this was necessary whenever there was palpable evidence that particular diseases were not sufficiently studied.

Sir WM. GULL referred to the frequency with which this subject came before the Council.

Dr. LYONS said the subject of mental diseases was, to his personal knowledge, often examined on at the King and Queen's Colleges of Physicians in Ireland. Hygiene and preventive medicine were likewise included in the same examinations.

Mr. TEALE explained that he had withheld approval from the suggestion of his two colleagues because he felt the danger of burdening students with another subject so extensive as hygiene unless its limits was most carefully defined for examination purposes.

After considerable discussion on the wording of the motion proposed by Dr. Banks, it was finally put as follows, and carried:—"That the subject of 'Mental Disease' be added to those of 'Hygiene' and 'Preventive Medicine' in the foregoing resolution."

Mr. MARSHALL moved, and Mr. TEALE seconded, "That the Council adopt the first seven paragraphs of Report of Council in Committee, and directs that they be transmitted with the Recommendations relating to oral examinations, mental disease, hygiene, and preventive medicine, to all licensing bodies."

Mr. TEALE moved, "That copies of the Visitors' Report, the Remarks by the Bodies visited, and the Resolutions of the Council thereon, be sent to all the Medical Authorities and Medical Schools of the United Kingdom."

Sir WM. GULL seconded the motion.

Dr. Watson, Prof. Humphry, Dr. Quain, and others, having spoken on the motion, it was carried.

REGISTRATION OF MIDWIVES.

The Report of the Committee appointed to consider the draft bill for registration of midwives was read and entered on the minutes.

ERASURES FROM REGISTER.

Dr. PITMAN moved, "That it would be desirable that, in any amendment of the Medical Acts, provision be made as regards persons whose names may be struck off the Medical Register, under Section 29 of the Medical Act (1858), that every such person shall *ipso facto* forfeit any medical title which he may at the time hold from any of the Medical Authorities; subject, however, to the further provision that any Authority, if it sees fit, may afterwards renew to such person the forfeited title on condition of its not being again registrable under the Medical Acts, except with the consent of the General Medical Council."

The object of this proposal was to remove an embarrassment which prevented the Council from acting as it might desire in all cases in which names had been removed from the Register. Many, if not all, of the licensing authorities were powerless to strike names off their lists under clause 29, and it was desirable to give them the power. Such amendment also would give the Council a power of restoration it did not possess.

Mr. SIMON seconded the motion.

Mr. TURNER said some bodies undoubtedly do possess power of removing names from their lists, but no University possessed such power of degrading graduates. The motion proposed to give power of renewal of such forfeited title with consent of the Council. This seemed a difficult matter in a legal sense. It might be that re-examination would have to precede restoration of a degree. Adoption of the motion would place enormous difficulties in the way of anyone desiring restoration to professional status. He could not vote for the motion.

Dr. STORRAR, while respecting Dr. Pitman's motives, quite saw the force of Mr. Turner's objections. The Universities would demur to an external body like the Council degrading their graduates. How would the Council treat graduates like those licensed by the Archbishop of Canterbury. Dr. Storrar thought the penalties inflicted under the Medical Act, which deprived a disregistered man of his professional privileges, met the necessities of the case. He would require to think the matter fully over.

Rev. Dr. HAUGHTON said the Universities could not be deprived of their privileges by any Act of Parliament. Dublin University found twenty years ago that they had no power to take away a degree once conferred.

Dr. HALDANE advocated deferring further consideration of the motion.

Dr. BANKS sympathised with the aim of the motion, but thought the removal of the name from the Register met the case.

Mr. MACNAMARA suggested that bodies not possessing power to take away licenses once conferred by them, should seek to have it. He thought the corporations would regard with a jealous eye the degradation of their licentiates by any body but themselves. He was sure any person

adjudged guilty of infamous conduct by the Council would find scant mercy at the Royal College of Surgeons of Ireland.

Dr. LYONS did not think any Act of Parliament with such sweeping clauses would ever be passed. The object held in view by Dr. Pitman was undoubtedly good as aiming at deterring all persons from criminality. But the practicability of his scheme was more than doubtful. His object might be obtained by the ventilation given to the subject by the discussion. It was to be hoped that the motion would not be pressed to a division.

Prof. HUMPHRY agreed with Dr. Lyons. It should be remembered that under the scheme of the Commissioners a University degree in medicine would not be included in the Register, and such a proposal as Dr. Pitman's could not then be entertained.

Mr. SIMON thought the purpose of the resolution had been served by the discussion on it. He thought the Universities ought to have power of degradation.

Dr. QUAIN referred to the case of Lamson, who had been accustomed to adopt titles to which he had no right. The Branch Council referred the case to the bodies which had licensed him, and these latter replied that they thought it was the duty of the Council to take away titles from practitioners guilty of infamous conduct.

Dr. PITMAN explained that his desire was to have the opinion of the Council expressed. All the corporations ought to have power of degrading persons who abused the privileges they possessed. The Archbishop's graduates could not be registered. He was willing to withdraw the motion.

Motion accordingly withdrawn.

Dr. AQUILLA SMITH moved to bring before the Council correspondence between the King and Queen's Colleges of Physicians and the Registrar of the Branch Council for England. The College accused a man named Prosser, holding diplomas M.R.C.S., L.S.A. Eng., who had performed a post-mortem examination, and on his evidence a verdict of manslaughter was returned. Subsequent examination of the body proved that the result given by Prosser was unsubstantiated by fact. He had not removed the organs. The College claimed that this conduct was infamous, and especially since an Irish practitioner, Mr. O'Leary, L.K.Q.C.P., had suffered false imprisonment through it on a charge of manslaughter. The College thought Mr. Prosser's conduct should be considered by the Council, under Section 29 of the Medical Act. The Council had at one time decided to complete the investigation of the case, and Dr. Smith, in consequence of the Branch Council for Ireland having declined to take action against Mr. Prosser, requested this might still be done.

Mr. TURNER urged that Dr. Smith was out of order. The case was closed, and could not be re-discussed.

Dr. SMITH said the Colleges of Physicians were dissatisfied with the inquiries made by the Branch Council, and were exceedingly anxious to carry out the investigation of the case.

Mr. TURNER insisted that any additional evidence must be laid before the Branch Council.

Dr. LYONS contended Dr. Smith was right in bringing the matter before the Council. The case was a most important one.

Dr. SMITH continued his explanation, and said that the Colleges of Physicians were very dissatisfied with the dilatory action of the English Branch Council, which had not taken any steps to make out the real facts of the case. Their College had done very much to defend the dignity of the profession; their Licentiates were required to observe strict professional etiquette every way. He moved that the Branch Council for England be requested to investigate the case of Prosser at once, and submit the result to the Council.

Dr. BANKS seconded the motion. The case referred to was most infamous, and ought to be thoroughly investigated.

Sir WM. GULL said, as a member of the Branch Council, he remembered that the case had been properly investigated, and it had been decided that not sufficient evidence was forthcoming to justify any action in the matter.

Mr. SIMON expressed a similar opinion.

Dr. LYONS said he had been much interested in the case, having been personally acquainted with Mr. O'Leary. He had been so impressed with the circumstances that he felt a public inquiry should be held into it. He was not at liberty to state the conclusion of this. The action of Mr. Prosser towards a professional brother was most regrettable. The consequences were too grave in character for the request of the College of Physicians to be ignored by the Council so far as regarded reconsideration of the case. No censure of

the Branch Council was intended, but it might be thought the Branch Council should have brought the subject to the notice of the General Council. He thought further attention should be given to the matter; he supported the motion to re-consider it.

Mr. MACNAMARA reminded the Council of the fact that the perjury took place in England. It might have been wise to bring the matter when it was fresh to the notice of the Public Prosecutor. Mr. Prosser was undoubtedly guilty of perjury. It was much to be regretted the Branch Council did not at once refer the case to the proper legal authority.

Dr. AQUILLA SMITH replied briefly, and insisted on the necessity for reconsideration of the case, especially since the evidence of Prosser was founded on a most imperfect post-mortem examination. The Colleges of Physicians had done all they could in the matter. He disclaimed any desire to impute any impropriety to the Branch Council.

Mr. SIMON suggested that additional documents relating to the case should be submitted to the executive committee, to be forwarded, if necessary, to the Branch Council.

The PRESIDENT said he quite thought Dr. Smith had acted within his right in bringing the matter before the Council. He explained that the Branch Council had acted on the advice of the solicitor to the Council. The action, however, was a distinct vote of censure on the Branch Council, which was wholly undeserved. If the Council desired the executive committee to reconsider the matter it would willingly do so.

Dr. SMITH denied any wish to move a vote of censure.

Dr. BANKS advised Dr. Smith to accept Mr. Simon's proposal to permit the Branch Council to receive further documents.

This course was followed.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 12, 1882.

THE COUNCIL'S ATTITUDE TO UNQUALIFIED PRACTICE.

FOR the first time since it came into existence, the General Medical Council seemed, early in the session just concluded, to be on the verge of performing an act which should both redound to its high credit and advantage the profession it is presumed to champion. For the first time there seemed a certain probability that acts already universally condemned by the voice of public opinion as well as by every honourable medical man, would meet the deserved punishment at the hands of those who are in strictest measure the guardians of professional interests. In a word, the question how to determine the future conduct of unqualified practitioners has come before the Council in concrete form, and the Council has decided—what? Not that the employment of unqualified persons is an indefensible act; not that unqualified practice is an enormity which it is a primary duty for it to suppress at all costs; not that the irretrievable injury done to the public by authorised quacks who are countenanced by qualified employers demands immediate and adequate attention; not even that it is a duty to prevent the repetition of flagrant improprieties by a stern exercise of judicial functions: but, instead of all this, it prefers to adopt an attitude of benevolent imbecility, and to those who are accused before it of practices grossly inimical to public and professional welfare it piteously exclaims, "*Please don't do it again.*"

It is impossible to regard the helplessly weak performances of the Council in respect to the several cases on

which it has been lately called to adjudicate with any other feeling than one of unmitigated regret. Nor has its conduct in any way been marked by the dignity which might have been expected from it while considering matters of such vital import to the profession as those which affect the relations existing between the latter collectively and its members individually. On Saturday week the Council was informally told that arrangements were made for the trial of a certain notorious case of professional misconduct before it, and that the following Tuesday was the day fixed for it to take place. On the Monday a more impressive announcement to the same effect was made, and on the appointed day of trial it is not too much to say that both the Council and the public were alive to the fact that something more than usually important was on the eve of occurring. The case, too, was sufficiently noteworthy to justify the excitement evoked. A duly qualified practitioner was accused of "running" four or five dispensaries, at several of which the charge of patients was mainly undertaken by wholly unqualified assistants. All the facts had been published in full in the lay press, and had been called forth as a consequence of grave malpractices resulting in such exposures as of necessity brought the owner of the dispensaries under the prominent notice and censure of the coroner's court before which he was summoned to appear. All the circumstances had been duly laid before the Medical Council, and even the examination of the principal delinquent in person afforded no suggestion in opposition to the opinion expressed by the Council when it adjudged him "guilty of infamous conduct in a professional respect." Notwithstanding, however, it forthwith proceeded to make the additional extraordinary statement that "the Council did not now direct the Registrar to erase his name from the Register," and the reason for this vicious clemency is that the acts complained of are to be discontinued.

Anything more disastrously injudicious than this unwise leniency it is impossible to conceive. The consequences will rest not simply on the Council, but to a vastly greater degree on the public about which it prates so exceedingly. Conduct more childish, more ridiculous, or more mischievous it could hardly be guilty of. In the most obstinate and intentional manner it proceeds on a course of the plainest self-stultification; in a single session, within a period of three days, indeed, it (1) declares that the employment of unqualified assistants is a great abuse, and must be inquired into, and appoints a committee to carry out that object; (2) it receives information of perhaps the most flagrant example ever offered of the condemned abuse, and declares by its collective voice that the person inculpated has been guilty of infamous conduct; and (3) forthwith forgives him for doing the very thing the Council has been at special pains to insist ought not to be done. If it is in this way the General Medical Council expects to verify its President's claims on its behalf, then the sooner the reformed constitution called for in it is effected the sooner will those who trade on the lives of the poor by practising in a manner to bring infamy on the profession be taught to respect the laws they persistently outrage. It is only too evident now that no assistance in putting down the villanous abuses that make the profession of medicine suspiciously regarded by the people can be looked for from those who are by

right and by appointment the guardians and the vindicators of professional honour. The Council is not desirous of exerting its influence in the direction of purification, if its recent decision is an index of its intentions; it probably considers that its time was improperly abstracted, by the case referred to, from consideration of matters relating to the examination of gentlemen, who, once they have responded to its ever-increasing demands in this respect, may, for all it cares, violate every provision in the code, outrage every feeling of an honourable kind, and, so that the Council be not thereby disturbed, play fast and loose to their hearts' content.

It may be that we are somewhat bitter in expressing the keen disappointment created by the wholly unexpected failure of the Council to carry out its imperative duty in the matter referred to. We confess to a hopeless despair of any good ever resulting from its action. The appointment of a committee to consider the abuses of the unqualified assistant system can be nothing more than a formal measure, for the vote of the Council on Tuesday indicates only too surely that, even should the committee report in favour of disregistering employers of unqualified assistants, these persons have too many "friends in council" to admit of such a measure ever receiving its sanction. To the energetic Association which was mainly instrumental in bringing the case referred to under notice, the result of its application to the Council must be peculiarly disappointing. There can be no doubt that this Association shared the general belief that the Council is in act as well as in theory the guardian of the rights of medical men; but it is at least satisfactory that such a mistaken notion has been effectually and for all destroyed, since so long as it was in existence time and labour might have been vainly bestowed in attempts to stir the lion to its work. Now, however, we know the Council declines to exercise a power which might injuriously affect the future well-being of persons who are guilty of infamous conduct in a professional sense; and so it will be evident, to such as may be, on the other hand, interested in maintaining the reputation of the profession, that in consequence of the Council's repudiation of its functions some efficient substitute for it must be devised.

It is a little unfortunate that the prospects of a new Medical Act are so remote, as the encouragement given to employers of unqualified assistants and others by the General Medical Council will, even in a little time, produce most evil results. This, however, must serve to stimulate the defenders of the profession to greater efforts; and it may be that they will be able to countervail the impetus to infamous conduct given by the Council.

VACCINATION AND SMALL-POX.

DR. SWEETING recently presented to the Committee of the Fulham Hospital a short memorandum on the subject of vaccination in relation to small-pox. In that document he traced the discovery and theory of vaccination; he adduced evidence as to its protective efficacy against and in mitigation of small-pox, and concluded with a review of the subject from a public health and medical point of view.

The circumstance is noticed by him that about the

year 1786, "from a chance remark of a Gloucester dairymaid," Jenner was led to the thoughtful observations and scientific experiments which subsequently led to the recognition of vaccination as a protection against small-pox. The fact that Jenner's views on some minor points are not held at the present day in no wise detracts from the practical value of his discovery. Neither at the present time are opinions in accord as to the identity or non-identity of cow-pox and small-pox, one school maintaining that cow-pox is only small-pox altered by cultivation in the cow; the other, that, although members of the same group, yet they are distinct diseases. With a view to illustrate the decrease of the death-rate in London since the introduction of vaccination, a table is inserted by which the general and small-pox mortality are shown during various periods of the last two centuries, the ratio of deaths calculated as per million inhabitants. That table presents several points of considerable interest. In the twenty years 1660-79, both inclusive, the ratio that deaths by small-pox bore to the general mortality equalled 5 per cent. In the thirty years from 1728-57 it equalled 8. In the first of these periods the general rate of mortality equalled 80,000; in the second, 52,000; so that as with the lower general death-rate of the second period there was a very material increase of that by small-pox. In the ten years 1771-80 the general death-rate having been 50,000, the ratio to it borne by small-pox was 10, in other words, an increase equal to 2 per cent. beyond that of the thirty years immediately preceding, the increase being ascribed to the practice of inoculation then so prevalent. Thus we have a total period of 120 years prior to the introduction of vaccination, and by striking the general averages for it, the circumstance transpires that, with a steady decrease of the general death-rate in London from 80,000 to 50,000, there was the very important increase in mortality by small-pox of from 5 to 10; also that with this notable decrease in the general death-rate of the populace, there was an actual numerical increase in the fatal cases of small-pox represented by the difference between 4,170 and 5,020, namely, 850 per million. It was during the decade 1801-10, that vaccination began to be practised. In it, with a general rate of mortality equal to 29,200, that by small-pox to the general mortality 6·20, although, as compared with the preceding period, the actual death-rate by small-pox according to population had decreased from 5,020 to 2,040—equal to 2,980 persons—the decrease being attributed to the circumstance that 30,000 individuals had undergone vaccination. The next period given includes the five years from 1831 to 1835. In it an increase in the general death-rate from 29,200, as above, to 32,000, but with a ratio thereto of deaths by small-pox equal to 2·5, as against 6·20 in the preceding year. And not only did this decrease take place as regards the relative mortality by small-pox, but also in regard to actual prevalence, the numerical deaths having been 830, as against 2,040, equal to a decrease of 1,210—that is, a continuation of the fall which is rendered apparent by a comparison of the periods 1771-80 and 1801-10. But surely there is some misprint in the memorandum where, in reference to this,

the fifth period of the series given, the statement occurs that "we find the general death-rate declining." As first noticed, it really increased; and that increase was, in a considerable measure, due to cholera. The next period given includes the ten years from 1841 to 1850. In it, with a general rate of mortality equal to 24,800—that is, about one-fourth less than that preceding—the relation thereto of deaths by small-pox equalled 1·6; the actual number, 400, as against 830. In the seventh period, namely, 1851-60, with a general mortality rate of 23,700—by small-pox 278—the relative proportion by the latter fell, but only to 1·17, which, with regard to actual decrease as compared with the previous period, amounted to 122 lives. The eighth and last period, statistics of which are given, is the decade 1861-70. In it the general mortality is 24,400, equal to an increase, as compared with that preceding, of 700, while the actual deaths by small-pox were 276, or, for statistical purposes, relatively 1·17, as in that preceding.

No doubt the author of the memorandum has reasons which to himself appear sufficient for selecting the particular periods he has given; for comparing some periods of unequal length; and for omitting others that would make the whole of those represented continuous. In the absence of information as to the nature of those reasons, however, the remark must be made that the omission is calculated to attract the notice of those who delight to take advantage of, and base theories upon, such loopholes. So, also, with regard to the omission of all particulars for the ten years including 1871 to 1880. Indeed, he appears to be aware of this himself, and he offers as an explanation for the omission the precise reasons which, according to the views of the majority of thinkers, ought to have decided him to enter into full details on the subject—particularly when reference is made to the ratios already noticed as given in his table. One of the reasons in question is that from the first to the third period shown, a steady rise had been in progress in the death-rate by small-pox, and from the latter, the date of which was antecedent to the introduction of vaccination as a practice, a decrease had set in which rapidly became more marked to the end of the eighth. He observes with regard to the period omitted by him, namely, 1871-81, that in it three epidemics of small-pox have prevailed, many of the cases in which were of such malignity as to recall the accounts of the mediæval "black pox." Of 113 cases of this description treated in the Fulham Hospital, 108 died; of those so treated, 55 only were registered as having undergone vaccination, and in not one of them was it well and properly performed. Perhaps, however, Dr. Sweeting may be induced to submit a further memorandum containing information in reference to the entire period from 1660 to the end of 1881. If so, the value of his statistical tables would be enhanced were he to give actual numbers as well as ratios as far as practicable in reference to population and mortality.

DR. MAPOTHER has succeeded Dr. Duncan as one of the medical officers of the *Maison de Santé*, Dublin.

Notes on Current Topics.

The Royal College of Surgeons, England.

ON Thursday last the election of three Fellows to fill vacancies on the Council caused by the rotation retirement of Messrs. Marshall, Power, and Baker took place. The result was what we have ventured to anticipate; Mr. Marshall headed the poll, the second and third places being occupied respectively by Mr. Power and Mr. Croft. There were six candidates for the three seats, the unsuccessful ones being Mr. Baker, Mr. Lawson, and Mr. Macnamara, of Westminster Hospital. It is said that the result will create feelings of disapproval in the minds of provincial Fellows of the College; but this can hardly be, since these latter showed so little desire to return their candidate, Mr. Baker, that they came up in the fewest possible numbers, the total number of votes recorded reaching only 246 out of 1,200. Moreover, the near success of Mr. Croft last year, and the freely-expressed opinions as to his almost certain return this year, made it a matter of the highest probability; and that this was admitted by country Fellows generally is shown by the ballot. Of Mr. Marshall's and Mr. Power's election there has, of course, never been any question; the contest has, in fact, been for the third seat, and of the four candidates none was considered to possess so favourable a chance as Mr. Croft, whose success is as satisfactory for the College as for himself. The following is the result of the polling:

Mr. MARSHALL	...	165	including	5	plumpers.
Mr. H. POWER	...	144	"	3	"
Mr. CROFT	...	103	"	21	"
Mr. A. Baker	...	72	"	10	"
Mr. G. Lawson	...	67	"	9	"
Mr. Macnamara	...	48	"	8	"

In the evening the Fellows' dinner took place, under the genial chairmanship of Mr. Prescott Hewett, F.R.S. Among the speakers were Sir James Paget, Mr. Spencer Wells, Dr. Statham, and Prof. Humphry. Mr. Spencer Wells spoke in a kindly manner of the President of the College, Sir Erasmus Wilson, whose absence he regretted on account of ill-health. He was glad, however, to say the President was now well enough to leave London for his marine residence, where he anticipated that his health would soon be sufficiently restored to enable him to return to his College duties.

Rapid Railway Travelling.

In these days of quick journeying it is possible that people forget under what circumstances exactly they perform the rapid transitions from place to place made possible by steam locomotion. Those practitioners, however, who are accustomed to receive the class of patients termed "nervous" observe frequent instances of injury directly traceable to the effects of quick train service, and especially is this so in the case of excitable or morbidly nervous "alarmists." There is a certain type of constitution which cannot undergo the strain put upon it by journeys made under the conditions necessitated by express travelling. Persons of this type, though they may not always show the state of mind they are in, are

nevertheless in constant terror of accidents, any slight occurrence, perfectly natural, perhaps, under the circumstances, but, nevertheless, differing from what obtains in slower trains, sufficing to arouse a nervousness of extreme degree, and so far, of course, exerting a harmful influence. Few people have not had some sort of experience to teach them the truth of this observation. The nervous traveller is an oft-selected object of ridicule for novelist and caricaturist; but it might advantageously be remembered that such persons deserve to be pitied and assisted rather than to be laughed at and abused. Their nervousness is as real and inseparable from themselves as any peculiarity of temperament. To them it might well be advised that they should abstain from incurring risks by which their susceptibilities would be irritated, and it cannot but be accepted that one potent risk of this kind is found in rapid travelling.

Charles Darwin Memorial.

THE executive committee of the Darwin Memorial Fund recently held a meeting at the Royal Society's Rooms, Burlington House, where the subscriptions received or promised amounted to £2,487. A decision was arrived at that a marble statue of the late naturalist should be executed, and a sub-committee was appointed to arrange for this being done. The site chosen for the statue is the large hall of the Natural History Museum at South Kensington, for permission to place it in which the trustees of the British Museum will be petitioned. The sub-committee referred to consists of Sir J. D. Hooker, Professor Huxley, Mr. W. Bowman, Mr. C. T. Newton, Sir F. Pollock, Mr. W. Spottiswoode, Mr. J. Evans, Mr. E. Dove, and Professor Bonney.

The Opposition to Compulsory Notification of Infectious Diseases.

WE are glad to observe that the profession is bestirring itself throughout the country for the purpose of offering a determined stand against the iniquity of compulsory notification. Last Friday a meeting of medical men of Liverpool and neighbourhood was convened for the purpose of forming an association for opposing "the compulsory notification of infectious diseases by medical men." A short time ago a circular was issued for signature by those opposed to the extension of this Act, which, it is alleged, had, in most instances, been forced upon the profession and upon the public without their knowledge, much less their consent, and in the space of ten days 184 signatures were obtained. At the meeting referred to, Dr. Wm. Carter, Physician to the Royal Southern Hospital, and Lecturer at University College, Liverpool, was chosen President and Secretary, *pro tem.*; Mr. R. Hamilton, F.R.C.S., Member of the Health Committee of the Liverpool City Council, Treasurer; and the following gentlemen were elected members of committee:—Drs. Adam, Costine, A. C. Hughes, Barr, Whittle, Nevins, Caton, and Bligh; and Messrs. R. Jones, T. D. Leigh, Manifold, McCheane, and Rushton Parker, of Liverpool; and Drs. Spratly, of Rock Ferry; Miller, Lamb, and Lambert, of Birkenhead; Fitzpatrick, of West Derby; Buck, of Leicester; March, of Rochdale; Macfie, of Bolton; Forsyth, of Greenwich; Murray, of Newcastle-on-Tyne;

Walker, of Bootle; and Cooper, of Widnes. The objects of the association will be to petition Parliament for the repeal of this Act in towns in which it is already in force, and to prevent its adoption by other towns, on the grounds that experience has shown it to be absolutely inoperative in preventing the spread of infectious disease, inasmuch as it leads to extensive concealment of the existence of such disease; that it converts medical attendants into so many spies, it being opposed to the well-being both of the public and of the profession that their office should be charged with such an odious duty; and that its tendency is to destroy the time-honoured and quasi-sacred relation that always has existed, and ought still to exist, between the sick and their medical attendants. Associations having the same object are being founded in various other towns, and it is expected that these will all be federated or united in one, and that as a body they will take active steps to oppose the action of the Parliamentary Bills Committee of the British Medical Association, which in this matter is said to be attempting to carry out a policy disapproved of by the majority of members of the Association. In this movement we can promise our warmest support; from the first we have not hesitated to stigmatise the attempt at compulsory notification as a degrading imposition on the profession and an interference with the trust reposed in it by the public.

A Cyprus Grievance.

THE Turkish journals of Cyprus have recently noticed a case in which it seems to us that a medical officer, acting under Government in that island, has been badly treated. We learn from *Non Kition* of May 27th that Dr. Cullen, who has had charge, as district medical officer, of the dispensary at Nicosia for some time, and who had qualified himself in the Turkish and Greek languages so far as to be able to dispense with the services of an interpreter in communicating with his patients, was, without any complaint whatever of inefficiency, or any explanation whatever, recently superseded by order of the Colonial Office, in favour of a novice who is absolutely ignorant of both the languages and the customs of the country, for whom the Government is obliged to salary an interpreter. The paragraph from the *Non Kition* is translated as follows:—

"It is with real sorrow that we hear of the removal of Dr. Cullen. Having discharged for some time the various duties attached to the dispensary, he succeeded in obtaining the esteem and good-will of the inhabitants. Possessing a knowledge of both Greek and Turkish, he was able to converse without the aid of an interpreter with the patients, and thus became a cause of economy to the Government, which finds itself now obliged to secure an interpreter, as the new doctor cannot speak himself to the sick. What becomes of Sir C. Dilke's promise, made some two years ago, that all future *employés* of the Government should speak one at least of the languages in use in Cyprus?"

The transaction seems to be one respecting which the Ministers for the Colonies might be able to give useful information if interrogated by some member who is interested in medical affairs. While the supersession of Dr. Cullen remains unexplained the Government lies under suspicion of a job and a breach of their own pledges.

Sanitary Primer Competition.

THE competition invited for a prize of £100, to be awarded for a satisfactory military sanitary primer, has not resulted in the production of a suitable work, and the prize, therefore, is not to be given to any one of the thirty-seven manuals sent in. The adjudicators have made the following remarks, which may, perhaps, have some value generally as indicating the view held by authorities on prevalent opinions: "We have examined the thirty-seven manuals submitted for competition, and are agreed that no one of them is, in all respects, suitable for the purpose for which a manual is required, as prescribed in the notification offering the prize. They all, more or less, contain theories regarding the causation of disease which are doubtful, and some of them are directly at variance with Indian experience. Their general tendency, moreover, is to exaggerate the dangers to health from local and climatic causes, and so to instil an unreasonable dread of Indian service." The last sentence is especially instructive.

The Council's Memory.

AMONG the many characteristic peculiarities exhibited by the General Medical Council, perhaps the most amusing to observers is the careful forgetfulness of its own performances invariably shown by its members. One result of this is pretty plain, and has been very clearly demonstrated in the recent session. It enables lengthy discussions to be carried on almost interminably, but to be at any time terminated by the announcement that Recommendation So-and-So already covers the ground of discussion. So frequently indeed does this sort of thing occur, and so fruitlessly is the time of the Council and the money of its constituents wasted thereby, that we venture to suggest the following "recommendation" for addition to those already existing:—"That it be a recommendation of the Council that members of the Council be requested to make themselves acquainted with the recommendations already adopted by the Council; or that, if this act of memory should be found too severe a tax upon the members, they will, previous to proposing new resolutions, convince themselves, by reference, that their suggestions are not already embodied in the 'Recommendations.'"

Smoking—Is it Injurious?

THERE is an energetic discussion now being carried on in the columns of the lay press which more than ever tends to show the wide diversity of opinion that exists on the effects of tobacco-smoking. The probable reason for this is that observers have arrived at conclusions on independent and misleading data—as, for instance, one observer may have noted the effects of a strong tobacco, and another the effects of a mild tobacco. Another very important factor in connection with smoking is the state of the pipe. When Raleigh and the older smokers indulged in the weed they had a large selection of pipes. They did not confine themselves to one, as so many modern smokers do. When the clay pipe went out of fashion, meerschaum and wood pipes came into vogue, and they have since continued to be the pipes in most demand. This, to a great extent, was not a good change. The old-fashioned churchwarden—still much favoured by those of the old school—is the

be an ideal of what a pipe should be. It is cool; the pipe-bowl is a long distance from the mouth, so that the curling smoke does not reach the eyes; it can be easily cleaned; it can be replaced at a very trifling cost; the smoke is exhaled in a more leisurely manner than can be done with the short pipe of the present day: and a good deal of the harm done by tobacco is attributable to the medium through which it is smoked. A pipe frequently used, and foul, must produce unpleasant symptoms. We do not wish to encourage smoking, but we have to deal with facts as they are. The public will smoke. Our patients will smoke. Medical men smoke. We must recognise these facts. Our duty is to advise smoking under the least hurtful conditions. We ascribe a good deal of the unpleasantness arising from tobacco to the use of foul pipes, foul cigar-holders, to holding cigars or cigarettes too long in the mouth. As a step towards obviating this, so that the tobacco of cigarettes—cigarette-smoking being now the fashion—can be burnt without any part of it touching the mouth, an American firm (Bovee and Adams, of New Orleans) has introduced what are called the corn-husk mouth-pieces. These mouth-pieces are attached to each cigarette, so that when one cigarette is finished the mouthpiece is thrown away, and a fresh one is used with the next. The holder is made of material that filters the smoke as it passes into the mouth, so that if there should be the slightest trace of nicotine it is retained in the corn-husk. We do not wish to be misunderstood. We have so frequently expressed our opinion on tobacco-smoking, that it is too late to alter our views. We look upon it with disfavour under certain conditions, as before puberty, when there is heart-weakness and other disorders. In some states it is beneficial; and as for several reasons cigarette-smoking is the best method, we feel it necessary to point out the way in which the dangers due to imprudent or excessive smoking may be avoided or minimised, by the latest American notion.

Viability of Premature Children.

PROFESSOR SPATH recently expressed himself as a believer in the very early viability of premature children (*Wien. Med. Zeitung*, May 20, 1882). After speaking of the generally accepted opinion that children were not to be considered viable until after the completion of seven lunar months' gestation—twenty-eight weeks (the Prussian law pronounces a foetus viable that has been carried thirty weeks)—he went on to say that his own observations warranted him in making the statement that foetus could be kept alive out of the sixth month even. Of course, the sixth lunar month is from the end of the twentieth to the end of the twenty-fourth week of utero-gestation. Particular care would naturally be demanded in bringing up such youngsters. Enveloping the child in cotton wadding was an admirable method of preventing loss of the low degree of body-heat such children possessed. The weakness of the digestive powers should be met by giving such milk as contains but a small amount of casein. As observation shows that the milk of women becomes richer in casein the longer they suckle, only young girls should be made choice of as wet-nurses who have been recently confined. It was

also necessary that the young person chosen should have long nipples; for as the infant itself would be too weak to suck and swallow, the nipples ought to project deeply into the mouth, so that the milk might in a manner run of itself into the stomach. Professor Späth himself had a case under observation in which a child born in the sixth lunar month was successfully brought up in the manner above stated, the child being at the present time six years old, and quite as well grown and strong as its brothers and sisters born at full term. He remarked, in conclusion, that the great mortality of premature children was easily comprehended when one bore in mind the ordinary high death-rate during the first year of infant life.

ON Wednesday last a gratifying presentation was made to Dr. Langdon Down by a committee that had been formed among the friends of that gentleman's patients at Normansfield, "to mark their great appreciation of the devoted care and skill their relatives had received at his hands." The testimonial took the form of an admirably-executed bust of himself in marble, by Mr. J. Sherwood Westmacott.

THE highest death-rates per 1,000 in the large towns last week from diseases of the zymotic class were—From whooping-cough, 2.0 in Bolton and 1.5 in Bristol; from measles, 1.9 in Huddersfield and 1.4 in Plymouth; from scarlet fever, 2.6 in Hull and 2.4 in Brighton; and from fever, 1.6 in Portsmouth, 1.5 in Bolton, and 1.0 in Hull. Of the 23 deaths from diphtheria, 12 occurred in London, 4 in Glasgow, and 2 in Liverpool. Small-pox caused 3 deaths in the outer ring of suburban districts around London; also 3 in Nottingham, 2 in Salford, one in Liverpool, one in Manchester, one in Leeds, and one in Hull.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 30, Bombay 20, Madras 29; Paris 22; Geneva 22; Brussels 24; Rotterdam 21, The Hague 14; Copenhagen 22; Stockholm 22; Christiania 19; St. Petersburg 48; Berlin 35; Hamburg 21; Dresden 23, Breslau 33, Munich 35, Vienna 23, Prague 35, Buda-Pesth, 39, Trieste 30, Rome 29, Turin 28, Venice 31, Alexandria 53 (51 deaths resulted from wounds inflicted during the riot of 11th June), New York 28, Brooklyn 23, Philadelphia 20, and Baltimore 21.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE CHAIR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.—The canvass for this chair is as keen as ever. Every one is sure that the candidate he supports will be elected. Every one admits that each of the candidates has peculiar claims of his own. Copies of testimonials have been flying about the city enough to obscure the few peeps which we have had of the sun for the last week. To analyse these literary productions would be impossible; but from some of them we learn that the appointment of one candidate "would

be received with the greatest satisfaction by the profession in England, who look upon him as the best man for such a post"; from another we are informed that the success of the candidate eulogised would "give general satisfaction to the profession on both sides of the Atlantic"—presumably from the Rocky Mountains to the river Ural. We have first and second series, and may, if the election is long delayed, expect a third, and even a fourth. Illuminated testimonials from students are being presented to the candidates; yet amid all this deluge of epistolary literature the seven Curators are expected to keep their minds "pure and undefiled," and to decide between the merits of the Transatlantic hero and him on whom England would look with delight. It is significant to notice that Mr. Chiene is supported by five of the University professors, and Dr. Duncan by two. There is, we believe, a general feeling in favour of Mr. Chiene, who, of all the candidates, has consistently devoted himself to pure surgery, and who has won many friends by his openness and genuineness of character.

"SHOP" IN THE UNIVERSITY OF EDINBURGH.—Dr. Cossar Ewart, the new Professor of Natural History in the University, appears to be very unpopular among a section of the students attending his class; and with all due deference to his undoubted abilities as a teacher and scientific worker, he has himself to thank, in some measure, for the annoyance to which he is so frequently subjected. It is not the first time we have felt it our duty to call attention to the sundry additions in the expenditure columns of students' fees to the Natural History Professor. With a class of 500 he can afford to behave more liberally than in suddenly discovering the fact that thirty diagrams are necessary for each student, and that thirty pence are an essential requirement of the Professor! And this, after the student or his long-suffering parents have already parted with 4 guineas for the Theory, 2 guineas for the Practice, and half a guinea for specimens of the science. It is not surprising, therefore, that Professor Ewart finds lecturing to turbulent students an unenviable task, and if he loses his temper, as he is accused of doing occasionally, and talks of "nabbing" or "nobbling" an offender (there is a discussion going on in an Edinburgh newspaper as to the exact expression), those who provoke such scenes must not be surprised. Far be it that we should for one moment be misunderstood as encouraging this opposition. We exceedingly regret that students should resort to ungentlemanly behaviour to ventilate their grievances. Such conduct is in the highest degree reprehensible, and always redounds on the heads of the disturbers. There is a legitimate form of agitation, which is more successful and creditable than "rowdiness," and we advise those who consider themselves aggrieved to state the same temperately and fairly in the proper quarter, and no doubt regard will be had to their complaints. Meanwhile, those who side with the professor, and are anxious to pursue their studies, are sorely put about in the attempt; and this, perhaps, more even than the disturbances, is likely to injure the reputation of the University, if the matter be not at once inquired into.

ANOTHER OUTBREAK OF FEVER AT CHAPELHALL.—On Friday morning another serious outbreak of fever was reported from Chapelhall, a village chiefly occupied by the workpeople of the Monkland Iron Company. Dr. Gibb, the medical officer of the works, has had eight new cases placed under his charge, and the fever is said to be of a somewhat aggravated description. Some time ago, on the suggestion of the local authority, Dr. Littlejohn, Edinburgh, visited the village, and reported as to its sanitary condition, and it was expected that matters would have shown improvement; but in the meantime these expectations have

not been fulfilled. The village suffers considerably from the want of a good supply of water, and the inhabitants are endeavouring to remedy this in the future.

APPOINTMENTS.—At the last meeting of the lecturers of the Glasgow Western Medical School, Mr. William Limont, M.A., M.B. Edin., was elected Lecturer on Physiology.—Dr. Macnaughton has been appointed medical officer to the parish of Glenelg, vice Dr. Stephen, recently appointed to the parish of Harris.

DEATH FROM FRIGHT.—For the past few days a large porpoise has been seen in the river near Innellan, much to the amusement of the residents and visitors, and many attempts have been made to catch it. On Tuesday night last week a sad affair occurred in connection with an attempt to secure it. While a large number of pleasure boats were out on the water the porpoise suddenly made its appearance alongside one of the boats, and a young lad who was one of the company in it was seized with a fit caused by the fright, and, before he could be conveyed ashore, died from the effects.

DR. GEORGE HAMILTON, OF FALKIRK.—We regret to learn of the death of Dr. George Hamilton, after a very brief illness, at his residence in Falkirk, on Wednesday morning last. Deceased had been in practice in Falkirk for about fifty years, and was held in high estimation by all classes of the community. Dr. Hamilton was much respected in the ranks of the profession for his urbanity, honesty of character, and literary acquirements. Besides his numerous contributions to the *British and Foreign Medico-Chirurgical Review*, the *Edinburgh Medical Journal*, and the *Obstetrical Journal*, he was author of several small treatises on scientific and popular subjects, including a text-book on animal physiology and a treatise on the steam-engine. He obtained his first degree, M.D. Edin., in 1833, so that he had arrived at an almost patriarchal age, and up to within a few days of his death was in his usual state of health, attending to the duties of his profession. He has left a family of three sons and four daughters, the sons being all members of the medical profession, one of them being the Professor of Pathology in the University of Aberdeen.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 1st inst., the mortality in Edinburgh was 80, and the death-rate 18 per 1000. About 40 deaths were due to diseases of the chest, and 6 to zymotic causes—1 measles; the intimations of this disease, 17.

DEATH-RATE OF GLASGOW.—The death-rate of Glasgow for the week ending with Saturday, the 1st inst., was 23 per 1000 of the population, compared with a rate of 25 per 1000 of the preceding week. For the corresponding week last year the rate was 24 per 1000, and for the same periods in 1880 and 1879 it was 23 and 22 respectively.

Correspondence.

COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you have replied to Mr. Collins's letter in your appended note, it may seem unnecessary to notice it further; but though you have well answered his main argument, you have not, I think, sufficiently exposed the fallacy of all his propositions.

In the first place, I deny that "the infringement of the rights of others is the only limit to be placed upon the rights of each." Mr. Collins surely knows that the law punishes those who attempt to destroy themselves; since drunkards and gamblers are under penalties, not merely because they infringe the rights of others, but because they are a danger to themselves. Mr. Collins assumes in his argument against compulsory vaccination, that all but a very few are vaccinated,

and therefore there is no danger to the majority from the small unvaccinated minority. But if vaccination were not compulsory, the minority would probably be much larger, and might even become a majority. If without legislation vaccination would be practised on all but a very few, of course there would be much less reason for compulsion.

In his final proposition Mr. Collins apparently argues that the Public Health Act is a sufficient protection against anyone who suffers from small-pox communicating the disease to others. What a blessing it would indeed be to the community if that Act were so efficient. Evidently Mr. Collins must be acquainted with pathologists who are unknown to the general profession, else he would hardly waste his logic in refuting certain people who consider that the "liability to a disease is contagious."

If Mr. Collins is really converted as to the medical value of vaccination I cannot but think that on further consideration he will come also to believe that compulsory vaccination is both justifiable and indispensable.

I am, Sir, yours faithfully,

SIDNEY DAVIES, B.A. (Oxon.), M.R.C.S.

Tottenham, July 5th, 1882.

THE ETHICS OF COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me, in response to your editorial strictures upon my remarks to observe that to my mind the idea of regarding unvaccinated persons as "potential sources of infection" of small-pox is an unreasonable one, for they can only be so in the same sense that we might say that those who have not had chicken-pox, scarlatina, or yellow fever are "potential sources of infection" of those diseases, or that a new-born babe is a "potential source of infection" of every zymotic disease under the sun. Surely that is an unnecessarily morbid view to take of mankind.

But, Sir, we legislate not for "potentialities," but for things as we find them; and the fact of having to plead "potentialities" as an excuse for compulsory legislation is, in my opinion, a sufficient reason for refusing to legislate at all.

You observe that "it is not a question of the unvaccinated endangering the vaccinated;" but when one learns that of 491 patients admitted to the London Small-pox Hospital only 21 were not vaccinated, it appears that your correspondent is not the only one who has "quite missed the point" of the argument.

I am, Sir, yours, &c.,

W. J. COLLINS, M.B., B.S., B.Sc. (Lond.)

Albert Terrace, N.W.

ERRATUM.—In the letter by Mr. Collins which appeared in our last issue, the word "loss" should read "law," in seventh line from foot, thus: "We abide by the law of equal liberties," &c.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.

THE monthly meeting of this College was held on Friday last, and, as there was a considerable distribution of the loaves and fishes, in the shape of no less than two King's Professorships, there was a great gathering of Fellows. For the King's Professorship of Physic, vacated by the resignation of Dr. William Moore, there were two candidates—Dr. J. Magee Finny, the present Registrar, and Dr. J. W. Moore, the former of whom was successful. For the King's Professorship in Midwifery, vacant by the lamented death of Sir Edward Sinclair, there were no less than six candidates, viz., Dr. John A. Byrne, Dr. J. R. Kirkpatrick, Dr. T. More Madden, Dr. R. D. Purefoy, Dr. Neville, and Dr. W. J. Smyly. After a prolonged and exciting contest, Dr. Kirkpatrick was declared duly elected.

HOSTILITIES IN EGYPT.

IN consequence of the commencement of hostilities by the British forces in Egypt, it has been found necessary to materially increase the medical staff at present at the disposal of Admiral Sir Beauchamp Seymour, and the medical arrangements of the department have now been definitely entrusted to Surgeon-General A. Smith, M.D., C.B., who has already seen considerable service.

Literature.

THE SPHYGMOGRAPH (a)

THIS interesting and instructive little volume opens with an historical sketch of the various methods of graphic observation and record of the pulse, commencing with the experiments of the Rev. Stephen Hale, B.D., F.R.S., Vicar of Teddington, in the year 1738, and ending with the sphygmograph of Marey, which may be said to have been the first appliance of the kind practically useful in ordinary medical work. Since the introduction of that instrument we have been steadily using the sphygmograph in one form or another, and therefore welcome Dr. Dudgeon's contribution to the elucidation of a favourite pursuit.

Marey's sphygmograph was difficult of application, and had the great disadvantage of having no means of regulating the pressure of the spring so as to ensure that different sphygmographic tracings were taken under the same exact conditions. The ingenious eccentric and dial added to the Burdon Sanderson and Mahomed instrument supplied this defect, but trouble was still given by the long arm of pear-wood, which was very liable to be broken, and the fracture of which necessitated a visit to the instrument-maker. In the third sphygmograph which we have employed this defect was obviated by the arm being made of a slip of thin cane which slipped into sheaths and could be replaced when broken by any one possessing ordinary mechanical dexterity—a small Japanese fan, costing a few pence, yielding enough cane for a lifetime. This instrument we used until Dr. Dudgeon's portable sphygmograph came under our notice; and we have since had recourse to the latter on account of its small bulk and consequent portability, its accuracy, and, still more, by reason of its dispensing with the long and awkward wooden lever.

In Marey's instrument an ink-pen wrote upon paper, but the pen seldom worked well. In the later sphygmograph a point wrote the tracings upon smoked glass; but this was inconvenient, because, although the tracing could easily be fixed by crystal varnish, it was unsuitable for the case book, and still more for the wood engraver. Dr. Dudgeon hit upon the excellent *via media* of using a point writing upon smoked paper. This can be fixed by varnish and gummed in the case-book; or, if so fixed, and pasted upon a piece of box-wood, the most rudimentary knowledge of wood engraving will enable the white tracing to be carved in, and so the block prepared for the printer. In our experience the Dudgeon sphygmograph is the easiest worked and most accurate of all these instruments. The pressure-gauge shows a range of from one to five oz. troy; and this is a pressure, in our opinion, quite unnecessary, and beyond what can be usually employed with advantage. We would suggest a pressure range of sixteen grams (under 2 oz. troy), and each gram to be divided on the dial into five parts, which would enable the eye to bisect each; we thus read them off as decigrams. Finally, the instrument is only one-third the price of the previous ones.

Passing by the historical or mechanical portion of the book, we come to the pathological section of the volume, commencing with a picture of the sphygmogram of the normal pulse (pp. 34-35), with detailed explanation thereof—an explanation which every scientific physician will endorse, and which is given in terms the clearest and most explicit. With regard to valvular disease, Dr. Dudgeon seems to think that the instrument contributes but little to our means of diagnosis. There is no doubt whatever that permanent patency of the aortic valves affords a most re-

(a) "The Sphygmograph: Its History and Use as an Aid to Diagnosis in Ordinary Practice." By R. E. Dudgeon, M.D. London: Baillière, Tindall, and Cox. Fcap. 8vo. Pp. 72.

liable sphygmogram, much more so, in fact, than any mitral affection; but we will go thus far with the author, and express our opinion that the sphygmograph will do but little in the diagnosis of purely valvular affections that cannot be equally well accomplished by ocular observation, by auscultation, or by digital examination of the pulse. In our experience one of the great uses of the instrument is in the diagnosis of the early stages of fatty degeneration of the heart. Every physician is familiar with the peculiar cardiac action and pulse incidental to the advanced stages of this affection, which is so justly dreaded by insurance companies. Rapidly mounting the stairs will, at an early stage, cause their temporary occurrence; but, in our experience, the sphygmograph displays them at a period when they are quite inappreciable by the best trained ear or finger otherwise. For this reason we never omit to use the sphygmograph in insurance examinations; and in this point of view we regret that the author does not enter into its relations with fatty degeneration. We have also obtained useful information in low fever, and in exhausting diseases generally; and we consider that the instrument has a future before it, particularly in its present improved state. We are aware that by many excellent physicians the sphygmograph is still regarded as a species of scientific toy; but the same has been said of many now well-established appliances. It is liable to error; for example, if a patient expire his breath for a few seconds and then make a deep inspiration he will occasion a very peculiar, and to some, alarming tracing, but such occurrences will not for a moment deceive the careful and practical observer.

University of Dublin.—At a meeting of the Senate, held on June 30th, the following degrees were conferred:—

BACHELOR IN SURGERY.—William Henry Burke, James Clute, James Seymour Carson, George Fredk. Dean, Benjamin Morgan Dockrell, William Francis Law, G. H. Longhead, Chaworth Louis Nolan, William Fletcher Moore Patton, George Blakeley Russell, John N. Seymour, Travers Robert Montgomery Smith.

LICENTIATE IN MEDICINE.—William Hamilton Allen.

BACHELOR IN MEDICINE.—Thomas Robert Bradshaw, William Henry Burke, Wm. Hallaran Bennett, Joseph Bulfin, William Alexander Carte, James Clute, Daniel Crowe, James Seymour Carson, George Frederick Dean, Benjamin Morgan Dockrell, George Lloyd-A-John, G. H. Longhead, Vicars H. Fisher, Robert Howard Fleming, William Francis Law, Michael McHugh, Charles D. Montray, Charles St. Stephen Richard Nason, Chaworth Louis Nolan, Alfred J. Rice Oxley, Henry William Peard, William Fletcher Moore Patton, George Blakeley Russell, John N. Seymour.

DOCTOR IN MEDICINE.—Thomas R. Bradshaw, Frederick Charles Berry, Abraham Cohen, William Lovel Hunter, Henry Malet, Charles Elghatt Trench.

MASTER IN OBSTETRICS.—Benjamin Morgan Dockrell.

Notices to Correspondents.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. WEBER-LIEL (Berlin) is thanked for his note.

DR. WISE (Newburgh).—We were unaware of the facts to which our attention is drawn; we will at once institute inquiries. Thanks.

A CORRESPONDENT (Spa).—The notes of "A Medical Man's Tour in the Ardennes" is unavoidably held over on account of the space occupied by the proceedings of the General Medical Council.

THE THERAPEUTICAL AND POISONOUS EFFECTS OF CARBOLIC ACID.—A correspondent at Scarborough complains of "the looseness of writers when advising the employment of certain drugs without giving precise directions as to doses, or proportions of dilutions." This, he says, "is frequently left to the uninitiated hands of those who have not previously tried them, and might lead to dangerous consequences." He refers particularly to the debate in our issue for Feb. 15th, page 139, "On the Therapeutical and Poisonous Effects of Carbolic Acid." Here, he continues, "the spray is diluted by one to 1 in 40, by another 1 in 20, and by others a stronger dilution is used." He desires to see more definite statements, and thinks it a paramount cause "that we make so little progress in therapeutics."

EAST END.—A correspondent thinks the following an appropriate stanza to certain notorious cases of unqualified practice:—

Our conduct's condemned by a few captious men;
Never mind! we have got it all snug;
Our title is spurious, illegal—what then?
Why, the public is ruled by humbug!

ONE INTERESTED.—The additional experiments were not contemplated in the original plan of the committee, and the unforeseen results arrived at prove that, unless these are completed, no accurate conclusions can be hoped for.

AN ANXIOUS STUDENT.—Our correspondent, if he is yet able to grasp the technicalities of the English language, will be much assisted

by studying the series of Histological Specimens with the literature of the subject which are now being issued by Mr. Cole.

MR. WILCOX will find the subject referred to in our leader columns; we are much pained at this dallying with unqualified practice by the official "guardians of professional honour."

QUESTER.—You are right in supposing Hunter, and not Anel, to have originated the operation of tying the artery for the cure of aneurism. Hunter conceived the idea from his well-known operation upon a deer in Windsor Park. He tied the carotid artery and noticed the effect on the formative velvet of the antler of the deer. The pulsation ceased and the velvet lost temperature. The animal was released, and about a week after caught and examined, when it was found that the circulation was re-established in the velvet. Hunter fancying that he had made a mistake in the operation, had the animal killed and the vessel injected, when it was found that the vessel was obliterated and the circulation re-established through collateral branches—a physiological condition then not conceived, but now readily comprehended by every student.

DR. E. DONALDSON.—Your paper on "Ophthalmic and Aural Practice" shall appear, if possible, in our next.

OCULIST.—Dr. Jacob's promised Lectures are unavoidably held over for illustrations.

A PATRICIAN.—We understand the Italian process of embalming to be as follows: 1. The circulatory system is cleansed by washing with cold water till it issues quite clear from the body. This may occupy from two to five hours. 2. Alcohol is injected so as to abstract as much water as possible. This occupies about a quarter of an hour. 3. Ether is then injected to abstract the fatty matter. This occupies from two to twenty hours. 4. A strong solution of tannin is then injected. This occupies for imbibition from two to ten hours. 5. A warm current of air passed over heated chloride of calcium is now made to dry the body. This may occupy from two to five hours, and the body is then ready for the final process, which is a secret.

DR. GRAY AND DR. A. W. WALLACE.—Early proofs will be sent you.

Vacancies.

Central London Sick Asylum District.—Assistant Medical Officer. Salary, £100, with board and residence. Applications to be addressed to the Clerk to the Managers, at the Asylum, Cleveland Street, Fitzroy Square, London, not later than July 15th.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Knowledge of the Welsh language is necessary. Applications to be sent to the Hon. Secretary on or before July 24th.

Hackney Union.—Assistant Medical Officer. Salary, £120, with residence, &c. Applications to be sent to the Clerk on or before July 15th.

Richmond Hospital, Dublin.—Resident Surgeon. Salary, £50, with furnished apartments, &c. Election, July 20th. (See Advt.)

Sussex County Hospital.—Assistant House Surgeon. The emoluments are £40, with board and residence. Applications to be addressed to the Secretary on or before July 26th.

The Guest Hospital, Dudley.—Resident Medical Officer. Salary, £120, with residence, &c. Applications to be sent to the Secretary not later than July 20th.

Appointments.

BRAMISH, W., M.D., L.R.C.S. Ed., Consulting Physician to the Cork Fever Hospital.

CONNELLAN, A. S., L.R.C.S.I., Medical Officer to the Bradwinch District of the Tiverton Union.

CROWTHER, G. D., L.R.C.P., L.R.C.S., Junior House Surgeon to the Halifax Infirmary.

FOTHERGILL, J. M., M.D. Ed., M.R.C.P. Lond., Physician to the Hospital for Diseases of the Chest, Victoria Park, London, E.

GRIFFITHS, P. R., M.B., B.S. Lond., House Surgeon to the Glamorgan and Monmouth Infirmary, Cardiff.

HARVEY, C. A., M.D., M.Ch. Dub., Extra Physician to the Cork Fever Hospital.

LAWRENCE, G. E., L.R.C.P. Lond., M.R.C.S., Medical Officer to the Workhouse of the Bath Union.

MCGEAGH, J. P., M.D., M.Ch., Resident Medical Officer to the Walton Workhouse, West Derby Union, Liverpool.

MCDONOUGH, H. A. H., M.R.C.S., L.R.C.P. Ed., House Surgeon to the Royal Hants County Hospital, Winchester.

Births.

DAVIES.—July 5th, at Jarrow-on-Tyne, the wife of Hugh W. Davies, M.R.C.S., of a son (stillborn).

KEYWORTH.—July 2nd, at Wem, Shropshire, the wife of G. H. Keyworth, M.B., prematurely, of a son (since deceased).

MOORE.—June 30th, at Killacoon, Clones, the wife of Thomas Moore, M.B., of a son.

WILLIS.—July 8th, at Gascony House, Hampstead, N.W., the wife of A. K. Willis, M.R.C.S., of a daughter.

Deaths.

BALL.—July 2nd, at Bruce Grove, Tottenham, Tertius Ball, M.D., Retired Surgeon-Major, A.M.D., aged 55.

BREW.—June 29th, at Pontrhydryn, near Newport, Mon., Charles Adams Brew, M.R.C.S., aged 62.

KERSWILL.—June 27th, at St. Germans, Cornwall, Robert Kerswill, M.R.C.S., aged 74.

KNAGGS.—July 3rd, at Stratford Lodge, Folkestone, Sydney Henry Knaggs, M.R.C.S., aged 45.

NEWINGTON.—July 3rd, Samuel Newington, M.A., M.R.C.P., of Ridge-way, Ticehurst, aged 63.

VALPY.—July 4th, W. H. Valpy, M.D., second son of the Rev. F. E. J. Valpy, M.A., late Rector of Garveston, Norfolk, aged 53.

A Course of Lectures

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

(Continued from page 23.)

LECTURE III. (concluded).

THE domain of Idiosyncrasy in respect to specific fevers is exceedingly important as regards both the physician and the surgeon, and I shall make no attempt to distinguish arbitrarily between their spheres in this matter. That which the surgeon is familiar with in the case of syphilis and those remote and exceptional consequences of measles, scarlatina, and small-pox which come under his care may be used to throw light upon the facts which fall under the observation of the physician in the earlier stages of these latter maladies. There is probably no good reason for believing that the specific animal poisons can vary in their intensity beyond certain narrow limits. Different epidemics of scarlet fever and small-pox do unquestionably vary somewhat, but after all, the limits of deviation from average intensity observed in different epidemics are as nothing compared with what we witness in different individuals attacked apparently under like circumstances. In the latter case we see constantly that it is possible for two individuals infected from the same source and with the same virus, the one to show an eruption consisting only of a few spots almost unattended by fever, the other to develop a confluent or even a hemorrhagic exanthem, which will prove fatal in a few days. Is it possible to give any explanation of these individual differences, excepting by attributing them to individual peculiarities, and when these peculiarities rise to an extreme height, can we name them more conveniently than as idiosyncrasies? I will endeavour to illustrate the subject by facts which have come under my

own personal cognisance. The portraits which I produce exhibit a gangrenous and ulcerative eruption which occurs in connection with varicella. They are, in fact, a peculiar form of varicella in which the eruption tends to persist and the individual vesicles ulcerate or become pustular. The evidence upon which I venture this unqualified assertion is, I think, conclusive, for this eruption has been observed repeatedly with the history that in the first instance it was supposed to be chicken-pox, and whilst chicken-pox was in the family and in a few yet more definite cases, the surgeon who identified the gangrenous case was the witness at the same time of varicella in its ordinary mild form in the patient's brothers and sisters. These facts have fallen under the observation not of myself alone, but of many others, and they receive important incidental corroboration from several narratives published long ago, and without full perception of the interpretation of the facts. My present object is to cite them simply in proof of the possible influence of idiosyncrasy in modifying the course of an exanthem. The case to which the portrait which I next show belongs was that of an infant to all appearance in perfect health, who had several brothers and sisters all healthy, who had all been vaccinated at the usual time with the usual results. In this child, however, vaccination was followed on the seventh day by a general eruption on the skin, which on the tenth day looked like ordinary small-pox, which subsequently became gangrenous, and caused death at the end of a fortnight. The state of the child's skin at the time of its death is well shown in the portraits. It will be seen to be covered by spots and patches of gangrene, the sphacelus involving the whole thickness of the skin. There is no form of variola known which in the least resembles this condition, and none will suggest, I think, that diagnosis. On the other hand, there is a well-known eruption, usually slight and mild, but occasionally very definite, which occurs after vaccination, to which the term vaccinia exanthem is appropriate. My suggestion is that this eruption bears the same relation to the ordinarily mild vaccinia rash which gangrenous varicella does to the common type of chicken-pox, and that its exceptional severity is due to individual idiosyncrasy.

I show next another portrait from a similar case which was observed by Mr. William Stokes, in Dublin, to whose kindness I am indebted for the portrait. The general facts were similar to those in my own case, with the difference that the eruption occurred a day or two earlier after vaccination, that the patches of gangrene were more irregular and more superficial, and that the child survived. I do not know that any

other examples of gangrenous vaccinia have as yet been published, but I have no doubt that such will in the future be observed. I have related some extreme instances illustrating the influence of idiosyncrasy in causing severity of exanthema which are usually very mild. Probably there are quite as striking examples of the converse, instances in which the specific animal poisons pass through the system and produce little or no obvious effect. It may be that these are much more common, and that they go far to explain some of the great apparent irregularities in the course of the exanthemata. We often meet with individuals who tell us that they have never had scarlet fever or measles for instance, although they were exposed in childhood at the same time that their brothers and sisters suffered; and we often see these diseases go through a family and leave one or more children apparently untouched. Still oftener will it happen that one or several individuals under such circumstances will show only a very slight febrile ailment, without any of the more characteristic symptoms of the disease, whilst others suffer severely. It has happened to me recently to witness a family epidemic of scarlatina which remarkably illustrates what I want to say. In mentioning its details, let it not be supposed that I think that it illustrates anything unusual; on the contrary, I believe that similar occurrences fall very frequently within the experience of those engaged in general practice. My facts are briefly these:—A child was affected with sore-throat and feverishness, but had no rash whatever, and beyond a slight fur no change in the condition of the tongue. She was well in a day or two, and nothing subsequently occurred to her. Four days later another child sickened with exactly similar symptoms, but more marked, and in her the usual rash of scarlatina soon appeared; a little boy went through the same course of events: both of these observed precisely the same period as regards the progress of the disease; both had nose-bleeding on same day, followed by rheumatism beginning in the same joints, the wrists, and both had great swelling of the cervical lymphatic glands. Subsequently an older sister, who was believed to have had it some years ago, went through a rather sharp attack. Thus, I take it, there can be no doubt that the disease in this instance was scarlet fever; but to prevent any question on that score I may add that one of the patients was seen by Dr. Gee. It is to what I have next to state that the chief interest attaches. The child who was the first ill, and who had but a day's sore-throat, no tongue affection, no rash, no peeling, was subsequently most fully exposed to the risk of infection, and did not take it, conclusively proving, I think, that the trivial illness she experienced was the fully-developed malady so far as her idiosyncrasy permitted it to show itself. But I have other facts yet more curious. Almost the whole family, and it was a large one, suffered one after the other, during the two or three weeks that the disease was in the house, from sore-throats and a day or two of feverishness. Several of them had never had scarlet fever before, and as to some others, it was doubtful. In all the cervical lymphatics swelled more or less, but in no instance was there the slightest peeling or any sort of sequela. I have yet to add that, when the first child had sore-throat, I was at once told that the family of a cottager living at a short distance from the house had just been suffering from similar throats. This cottager was the milkman, and apart from this fact, there had been personal communication between the two houses. On inquiring at this cottage, I found that the father, mother, and two grown-up daughters had all in succession had sore-throats, attended with a day or two of rather sharp febrile illness, but in no single instance had any rash been observed, nor had any peeling of the skin followed. They were not known to have had scarlet fever on any former occasion, and laughed at the suggestion that what they now had was it. It may be that after all it was not, but the dates fitted well with the possibility that the first of the children affected had got the contagion from this source. The inferences which I wish to draw from such narratives as this is that it is possible for the individual peculiarity of patients—a peculiarity which may be hereditary and may affect many individuals in the same family—to so far modify and minify the course of an exanthematic fever as to make its recognition quite impossible; that we ought to seek for the explanation of these remarkable differences, amounting in many instances to almost total suppression, not in differences in the degree of epidemic virulence, nor in the hygienic surroundings, nor in anything which can properly be called the state of health of the patient, but in that of which we can give no other explanation than that it must rank as an idiosyncrasy. It is needless to point

out what a pitfall of fallacy is here opened for the feet of the investigator. How easily may we find ourselves attributing to influences which were wholly inoperative results which must simply be put aside as those which we ought to expect under the known laws of idiosyncrasy. I will leave for the present the examination of those laws as they influence the course of another specific fever. This is the time at which I ought properly to mention the facts which in the case of the specific fever known as syphilis illustrate its extreme inequality of incidence in different persons. I must not, however, enter into any details, and I leave them aside the more willingly because the facts to which I refer are matters of universal knowledge. We all know how differently chancres behave in different persons; how they may become phagedenic or sloughing without our being able to assign any cause for the difference. We know, also, that the syphilitic rash in many cases is wholly omitted, together with the rest of the train of secondary phenomena. We know also how, when secondary symptoms do appear, how infinitely variable they may be in form and in severity. A roseole, a lichen, a psoriasis, a rupia, an eruption indistinguishable from variola—such are a few of the forms which we frequently see. Impressed by these startling differences, good observers have tried to make out that there are different kinds of virus, but all the facts are in opposition to such hypotheses. I must content myself by suggesting that they are due to inherent differences in the individuals who receive the virus, and must pass on to other topics. Let me next remark that, not only is the sphere of individual peculiarity almost unbounded in its power of modifying the force of the primary outbreak of an exanthem, but that it exercises a great influence in determining who shall and who shall not suffer from complications and sequelae. Under this latter term I am alluding rather to what may be called accidental sequelae; the inflammations of various organs and parts which occur exceptionally and at some little distance of time, and which often bring the patient under the care of the surgeon. The peeling of the skin, and possibly also the nephritic desquamation which follows scarlatina, and are sometimes classed as sequelae, are really parts of the primary disease. As I think my narrative has conclusively shown, peeling of the skin is not a sequel of scarlet fever *per se*, but of one of the symptoms of scarlet fever, namely, of dermatitis, to which it is always proportional, and of which it is the necessary consequence. Inflammations of the ears, and of the bones or joints, stand, however, in a different category, and so does the ophthalmia tarsi, which often follows measles, and the pruriginous affections of the skin which are not infrequent after both vaccinia and varicella. When these events occur, they occur probably not by any means as necessary parts of the disease, but rather as revealing idiosyncrasy in the individual. Inflammations of the ear and allied affections may possibly in some instances reveal diathesis rather than idiosyncrasy. That is, it may be that they occur because the patient is distinctly scrofulous, or the subject of some other form of recognised ill-health. Even as regards them, however, I much doubt whether this is always true, and respecting the affections of the skin to which I have referred, I am sure that they often occur to those who are in good health, and that they are proof of idiosyncrasy only. Variability in the degree of irritability of the skin is common, and may proceed to great lengths. Flea-bites, woollen clothing, nettle-stings, and the like, produce on different persons extremely different results. Urticaria is a form of dermatitis of which probably but few persons are susceptible, and in those in whom it occurs it demonstrates or reveals this susceptibility and nothing more. The patient who gets nettle-rash whenever he eats lobster may yet be able to digest lobster with as little inconvenience as other people. It is his skin, or perhaps the nerves of his skin, in which the susceptibility alone lies. In this suggestion rests, so far as I can see, the real explanation of the maladies which have been grouped together under the name of prurigo. There is no one disease to which the name is applicable. What we see is the power of various sources of local irritation in provoking pruriginous dermatitis in those in whom idiosyncratic susceptibility exists. Now it is the presence of pediculi; in other cases of fleas; in yet others the presence of an exanthem, such as varicella, which is the starting-point; whilst in all, the morbid condition, once initiated, is kept up by the patient's unwise efforts to relieve it, and by the mere fact of its having got possession. I repeat, there is no such disease as prurigo—a malady which has been described by a high authority as if it were self-existent, alike causeless and cureless, but there are plenty of persons

born with that peculiar irritability of skin in which a variety of causes may evoke the symptoms to which the name has been given.

We may probably with much confidence place diphtheria and erysipelas side by side as diseases, or rather type forms of the inflammatory processes which obey parallel laws. Probably no human being is exempt from the liability to them, but at the same time it seems certain that the degree of proneness varies very much in different individuals, is persistent through life, prevails in families, and is matter of inheritance. Thus, then, we attest for both the existence not unfrequently of a sort of constitutional predisposition to which the terms diathesis, or even in some instances, that of idiosyncrasy, is applicable. Both may become contagious, and of both exposure to direct contagion is probably by far the most efficient mode of production. Many persons will take them by contagion in whom other causes would have proved abortive. But both are capable of spontaneous origin and, to speak more correctly, may be produced by exposure to certain non-specific influences, such as the ordinary causes of catarrh injuries, sewer gas, and some others. It is most important that all who value accurate classification should deny both as regards erysipelas and diphtheria their right to rank with those fevers which are due to specific animal poisons. With these, as it seems to me, neither of them has any real affinities. In both, I repeat, it is a personal and inherited peculiarity, giving proclivity when certain exciting causes are brought to bear to peculiar forms of inflammatory action with which we have to deal. In both the disease is probably local at its origin; in both it spreads locally, and the contagion of continuity of tissue and with both constitutional symptoms result which are in some ratio with the extent and severity of the local action. Neither of them in the least protects the individual from future attacks; indeed, although in each single attacks are common enough, yet it is generally acknowledged that those who have suffered once are more prone than others to suffer again, and in both there are not infrequent instances of proclivity lasting through many years. In erysipelas the essential feature is a spreading inflammation of lymphatic spaces in the skin producing goat oedema, and usually great dilatation and enlargements of blood-vessels. In diphtheria we have a spreading inflammation of a mucous membrane, attended by oedema, great dilatation of blood-vessels, and the formation, in greater or less quantity, of a fibrinous pellicle. Although I mention skin as the seat of the one and mucous membrane of the other, let it be distinctly understood that these are only the most usual sites; both may attack cellular tissue or wounds, and each may occasionally affect the usual territory of the other. There may be some doubt as to how, when these inflammations affect repeatedly the same individual, the fact should be explained. It may be that one attack leaves a really increased proclivity to a second, or it may be that the first simply revealed a proclivity which had existed all along, and of which the later ones are merely the manifestations without addition. Probably both explanations are true. It is, I presume, not necessary that I should produce before this audience any citation of evidence in proof that a personal liability to erysipelas and diphtheria may be witnessed. All are familiar with them. It is probable that there are some slightly marked affinities with the diseases just named and such maladies as carbuncles, and boils, and acne. Respecting all these, we have the same questions to ask, how far are they dependent upon constitutional causes? and, how far upon those which are local? We may take it as certain that in all there is a double causation, and our task is to assign in each instance the relative share of each. In the first place, we may say that the liability to acne, to boils, to carbuncles, is often a family matter, and is seen to occur with unusual frequency in relatives. It is often also a personal matter, as is proved by its persistence or recurrence at various periods of life. Further, the association of these maladies with more or less temporary disturbances of health, with diabetic dyspepsia, with constipation and defective tone, is a matter of constant observation. Whoever has reflected, however, as to the real value of carbuncular inflammation will, I think, see reason to believe that its peculiarities are to a large extent local ones. Respecting both boils and carbuncles, it is the fact that the most efficient measures of treatment are those which appeal to the local condition. This is true of all the different

measures in repute, however dissimilar at first sight they may appear. Some have for their object the protection of the inflamed area from further irritation, as when we cover up a boil or commencing carbuncle with leather plaster, others, the subduing of the inflammation by means of cold and the like, as when we use an ice-bladder or a strong spirit lotion. Nor do those who adopt a time-honoured practice of an early, free incision depart from this principle, for their object is still the mitigation of local inflammation by the relief of tension, and by permitting the escape of contaminating matters. From acne, impetigo, and ecthyma to boils is in many cases a matter of degree, and that there is little or no real distinction between a large boil and a small carbuncle, all will, I think, admit. The age of the patient, and his special dietetic condition at the time, place, the influence of different modes of local treatment, are the conditions which determine the final result. If a boil occur in an elderly person, on the nape of the neck, where it is likely to be irritated by the shirt-collar, and especially if, instead of being systematically protected from the first, it be further bullied by premature squeezing and the like, it is very likely to pass on into a carbuncle. I claim the strong testimony which has been borne by Sir James Paget and others to the efficiency of simply protective measures in preventing the development of small carbuncles, and obviating the supposed necessity for incision, as proof that local spreading is, in the main, due to local causes, and has no necessary connection with the general health. In other words, it is not a thing which is inevitable. On the other hand, we know of no internal remedy which possesses any marked power in arresting carbuncular inflammation. If now we ask, In what does the peculiarity of carbuncular inflammation consist? in what does a carbuncle differ from a boil? I should be inclined to reply that it is solely in this tendency to spread. The spreading is effected by contagion of continuity, and it has certain marked resemblances to what we observe in erysipelas. A carbuncle might almost be defined to be an erysipelatous boil with the proviso that the expression is not intended to imply identity of inflammatory type, but only close similarity. Throughout its whole course, and however extensive it may be, carbuncle in combination with its erysipelatous method of spreading retains the characteristics of the furuncular process. Its secretions and its core, or slough, are exactly like those of a boil, excepting that they are much more abundant. In a general way there appears to be a natural tendency independent of treatment to the arrest of the process, and this is not generally observed in erysipelas. In other words, erysipelatous inflammation is more intensely infective than is carbuncular. I must, however, qualify even this admission of difference by reminding you that carbuncular inflammation has such an injurious influence on health and in all cases in which its spread continues in spite of treatment, that the patient quickly dies. Thus many cases occur in which no proof is given of tendency to arrest. It may easily be the fact that in some states of system and some types of carbuncle there is as little tendency to arrest as there is in phlegmonous erysipelas. I fear I am wandering rather far from the subject of diathesis, but my argument, if I have succeeded in making it clear, is this: that there exists a certain state of tissues and constitutions different in each instance, which gives proclivity to erysipelas, to acne, to boils, and carbuncle, and that while the importance, the almost paramount importance in many instances of local influences in exciting and aggravating the diathesis in the background must not be forgotten. Further I have argued that carbuncle is the result of a sort of combination of the erysipelatous and furuncular types of inflammation. I feel sure that these views as to pathology will be found to fit well with therapeutics. Tetanus is a malady so rare, that if we admit its possible spontaneous production without regard to previously existing proclivity, we must not expect to find many instances in proof that the latter does sometimes exist. Yet there are such, and possibly if looked for more than we might suppose. The influence of race is proved by the great liability both of infants and adults amongst the negroes, and also of certain animals. I have met with a few cases in English practice of what appeared to imply that there might be an inherited proclivity to tetanus. A man who looked quite well walked into my room as an out-patient at the Metropolitan Free Hospital and gave me his own diagnosis by declaring "I am going to have lockjaw." I found that

he recently had a slight wound on one hand, and that he was beginning to feel some stiffness of his jaws. His symptoms, however, were exceedingly slight, and his anxiety was caused by the fact that his father had died of tetanus. The poor fellow's foreboding was rapidly realised, and he died within a week.

Here, however, for the present, gentlemen, I must take leave of the subject of idiosyncrasy. I have endeavoured to claim for this form of individual peculiarities a much wider sphere of influence than is usually accorded to them. It is necessary, I am well aware, that one should exercise some scepticism in accepting doctrines of the kind I have brought before you. To fall back on the suggestion of an idiosyncrasy is so easy that it may easily become the resort of intellectual sloth. We must not, however, be deterred by this consideration from the acceptance of such doctrines if they are true. That they are so within certain limits I cannot doubt, and the problem before us is to find those limits. If we begin to recognise, or if we forget the all-obedient influences of idiosyncrasy, we shall not only waste much time in processes of clinical research, but we shall be in constant danger of coming to wrong conclusions by declining to accept evidence as to causes which is really sound, and of adopting false principles in reference to treatment. In every example of curious and unexpected form of disease, our minds should, I think, first ask the question, "How much of this may possibly be due to the individual peculiarities of its subject?" We are often on a wrong track if we seek to make external influences explain the whole. Let me add, in conclusion, and it seems to me of great practical moment, that the individual peculiarities of all patients should be carefully studied, and that they should be made intelligently acquainted with them. There are few of us without our idiosyncrasies and their variety is innumerable. If it should become the custom to record some sort of life-history in permanent form from the birth or infancy onwards all the peculiarities in an individual as the result of medical observation, not only would much be done in the way of preventing subsequent errors in treatment, but valuable contributions would be made as to a knowledge of the real nature of many diseases. It is not only as regards the prescription of many drugs that a knowledge of our patient's peculiarities becomes important to us in practice, but the advice we have to give in respect to places of residence, mode of life, and of general management are often of far more importance than the medicine prescribed, and its wisdom or the reverse may depend on the knowledge or the ignorance of the individual peculiarities, and those peculiarities frequently do not display themselves in any of the symptoms, and can be recognised and revealed only by a correctly-kept life-history.

Original Communications.

FROM THE RED SEA TO THE NILE, JUNE AND JULY, 1801.

By Surgeon-General CHARLES A. GORDON, M.D., C.B.,
Late in Medical Charge of Her Majesty's Forces in India, and
Special Commissioner during the Franco-Prussian War.

WITH the prospect before us, it may be, of a protracted and arduous campaign in Egypt, the following particulars regarding the march of British troops through the Desert in the months of June and July, 1801, have a suggestive interest at the present time.

On the 6th of June, 1801, at 6 p.m. the 86th regiment began its march from Suez towards Cairo. Each man carried three pints of water. After marching two hours in the desert, two officers had become so ill as to be unable to continue their journey farther. At eleven o'clock the troops halted for two hours, then resumed their march until seven in the morning, by which hour they had completed 26 miles. The day of the 7th became intolerably hot. Tents were pitched, but at 10 o'clock in the forenoon the march was resumed, as it was feared that delay would render the camels so weak that they would be unable to proceed without water. The thermometer stood at 109° F. An officer fell behind, and men dropped fast to the rear. About one o'clock a halt took place. Baggage was cut from the camels, and the animals were sent back for officers and men who were unable to keep up. The force then proceeded.

The kamseen began to blow; the thermometer rose to 116° F.; officers and soldiers were seized with giddiness and dreadful sensations; many fell down gasping, and calling for water to drink. At four o'clock p.m. they halted. The water skins cracked by the sun, the water became of a thick consistence; to drink it caused violent pains and vomiting. The officers shared with the soldiers some wine and spirits which they mixed with the remaining water. In the evening the wind ceased; the air became temperate. At seven o'clock, p.m. the march was resumed; seventeen men were left on the ground, and camels left to bring them on. At eleven, p.m. they halted. Officers and soldiers were so much exhausted that sleep immediately fell upon them. At four a.m. of the 8th they again started; the limbs of many among them benumbed by the cold of the previous night. The kamseen began to blow as it had done the previous day; but the men were less affected by it. At four o'clock, p.m. they reached the springs of Elkana. By 8 o'clock all the camels had come up, and the men who had been left behind rejoined during the succeeding night with the exception of nine who perished in the desert. No man had partaken of food since leaving Suez, as their salt rations would have increased their thirst; their salt pork had accordingly been thrown away by them on the first morning of their march. On the 9th of June the troops marched from the springs after nightfall, in order thus to avoid the enemy. At 11 p.m., on the 10th, they joined the Turkish army at Chubra. The soldiers had suffered the loss of their uniform, it having been burnt on account of the plague. They had also to abandon their knapsacks, which they carried when they began their march; and thus, on arriving at Cairo, such was the appearance presented by the men who had performed the journey from Suez that, according to the reports from which these particulars are gathered, "it excited great interest."

A second body of troops began their march from Cosseir at 6 o'clock on the afternoon of 18th July of the same year. The heat was intense. After marching five miles they reached a black rivulet of bitter water. Thirst was intense. They drank, but some experienced the effects of their folly; they fell back faint and oppressed; what air that did exist was like the breathing of a furnace. At midnight they reached the new wells. A guard was put over the wells; the men were ordered to lie down. At daylight (of 17th) their camp was pitched. Thus for ten days their march continued to the Nile, which they reached at Kenna, many men falling behind as they proceeded, and having to be brought on on camels. By the orders of General Baird, wells had been sunk in the Desert as far as it was possible to do so. The difficulties attending this route appear accordingly to have been much less than those to which the first-named force were exposed on their march from Suez to Cairo.

REMARKS ON OPHTHALMIC AND AURAL PRACTICE.

By E. DONALDSON, B.A., T.C.D., &c.,
Medical Officer of Burt District.

THE following remarks have been suggested by the experience of the writer in over 300 cases of ophthalmic and aural diseases. By far the most of these cases occurred within the last year and a-half. The writer himself is a general practitioner, and has no pretensions whatever to the refined knowledge of the specialist. For this reason what he writes will, perhaps, be the more readily attended to by other practitioners.

Of all men general practitioners most require all the aids that modern science has brought to bear on the diagnosis of disease. These aids render diagnosis easy. With a little knowledge of the use of the instruments of precision, a man of feeble diagnostic power can do more to find out the nature of many ailments than a

man of Sydenham's genius can do without them. "A dwarf behind his steam-engine may remove mountains, but no dwarf will hew them down with a pickaxe; and he must be a Titan that hurls them abroad with his arms." If any class of men can do without using the aids we now possess for diagnosis, specialists—not general practitioners—can do so.

There are great inducements to medical men to attain to a little proficiency in eye and ear cases. 1. Their reputation depends to a great extent on the way they manage these cases. 2. The trouble required for attaining the necessary information is not great. 3. A great deal of satisfaction will result from treating any of these cases to a successful issue. 4. Patients are greatly benefited by such proficiency. How easy it is to acquire a great deal of useful knowledge the following remarks will show.

Ophthalmic practice naturally divides itself into three great branches, according as it deals with the operative surgery of the eye, the correction of errors of refraction, and the treatment of all other diseases and inflammatory states of the eyes. The first two are, to a great extent, very justly left to the care of the ophthalmic surgeon. To the last, in which will be found the greatest number of cases, I propose to confine my remarks as much as possible. This class contains the cases the general practitioner is often called upon to treat. In the great majority of the cases no very special skill is required. Strumous ophthalmia is by far the commonest disease of the eyes I have met with. In some cases local treatment gives the most brilliant results, while in others it appears to be of little use. In the latter cases the constitutional disturbance seems to prevent the local remedies from having the required effect. Of all the local remedies I would certainly give the palm to atropine. One can scarcely go wrong in prescribing it. When I am called on to treat a case of strumous ophthalmia in a child or adult, I, as a rule, prescribe atropine for the first day or two, and then cautiously add to the treatment the local application of calomel or ung. hydrarg. ox. flav. If the last two remedies cause too much irritation, I stop them at once, and almost entirely rely on atropine. Some cases are exceedingly difficult to cure. One case of a child, *æt.* 5, came before me in March last, in which, in addition to the remedies mentioned above, I tried eserine and paracentesis of the cornea. Constitutional remedies—cod-oil, tonics, an occasional purge—were prescribed. After a long attendance and little benefit the mother ceased to bring her child. It must be remarked, however, that the mother, although she displayed greater perseverance and care than most dispensary patients, did not fully carry out instructions.

On one occasion I was consulted by a well-to-do shopkeeper's wife. She had previously been under the care of her regular medical attendant. I found that she suffered from a partial staphyloma of the cornea, the result of an ulcer, and that the treatment that had been adopted was not calculated to better the condition of the eye. I ordered a compress bandage and eserine. As the bulging remained stationary, she determined to consult an oculist in Belfast. She did so, and was advised to continue the bandage. It was suggested that iridectomy ought to be performed if the bulging increased or the sight failed. What great skill was required in ordering a compress bandage in this case? Yet owing to the want of it, the reputation of a practitioner in eye diseases, at all events, suffered. The compress bandage has also proved of use in ulcers of cornea and in injuries of the eyes.

A few cases of iritis, badly treated from their own neglect, and occasionally from the want of knowledge of their medical attendants, have been observed. If all practitioners would never treat an eye without first trying to make a diagnosis, and if they would use atropine when in doubt, there would be fewer cases of adhesion of the iris to the lens. The evidence of iritis

is usually clear enough, so that there can be no doubt; but if the diagnosis is difficult, I advise the practitioner to examine the tension of the eye, and, if it is normal, to instil atropine. Most probably he will do his patient good, and clear up the diagnosis.

Two cases of granular ophthalmia came before me. In one case it was possible to make a diagnosis at a glance. The drooping of the lids, and the redness of their edges, combined with the information given by the patient that she felt as if something were in her eyes, rendered the diagnosis almost certain. Closer inspection and eversion of the lids confirmed the opinion. Cases of this kind are occasionally mistaken, and consequently badly treated.

A large ciliary staphyloma is a very unsightly affection of the eye. I have known it to be mistaken for malignant disease.

Dryness of the mouth and throat in one case followed the instillation of atropine. A woman consulted me for cataract. I instilled atropine to see if the lens were ripe. She on her next visit, of her own accord, informed me of the decided effect the drug had on her mouth and throat.

In one case paralysis of the accommodation after diphtheria gave rise to a good deal of anxiety in the parents' minds. They feared lest the boy was becoming blind, as he could not read. Had the true nature of the ailment not been recognised, the parents would have undergone the expense of a journey to a specialist. This case has been published elsewhere. Paralysis of the accommodation from atropine every practitioner has seen, and there can be no excuse for not recognising the same condition after diphtheria.

The lower canaliculus can be slit up without any difficulty. I know of one case of chronic catarrh of the lachrymal sac which had been frequently poulticed, and which at once derived great benefit from simply slitting up the canaliculus. I have found great benefit from this little operation in cases of chronic conjunctivitis in old people where the lower lid has fallen away a little from the globe. It proved of great service in a case of lupus where the lower lid was somewhat displaced. I have not yet derived much benefit from probing the nasal duct; perhaps from want of the necessary skill.

In some of my cases the ophthalmoscope has been found to be of the greatest practical value. Opacities in the lens and vitreous, which could not be seen by the naked eye, were easily seen. The haziness that somewhat resembles cataract was, on more than one occasion, shown not to be due to an opaque lens by aid of the mirror. A sailor was once sent to me by a medical man to examine his eyes. This sailor said he was short-sighted, and claimed a pension, as he was no longer fit for his calling. It was very important that the fact that he suffered from myopia should be clearly proved. By the use of the mirror I saw the vessels at a distance. This was enough to prove to me that there was something wrong with the refraction of his eyes. One lesson on the use of the ophthalmoscope would be sufficient to enable any practitioner to know that this man was no pretender. By means of lenses I also ascertained the correctness of his statements. Very little trouble or expense will enable anyone to learn for himself the good of the ophthalmoscope. I can scarcely understand how any man can undertake, without the aid of the ophthalmoscope, the treatment of a case of "amblyopia" in which there are no changes in the eyes visible by ordinary inspection. Yet I have known this to happen. Such a practitioner would surely feel that the ophthalmoscope is of use, if he were only aware that it could lift some of the darkness from his own eyes.

In aural work some success has followed my efforts. Some cases which have been for a long period deaf have not been at all benefited, and the diagnosis in these cases has, I confess, not always been beyond question.

Necessarily my attention has been often drawn to syringing the ears. I find that some practitioners, when anyone complaining of deafness comes under their care, at once resort to the syringe. If wax comes out, and is the cause of the trouble, all is well and good. If not, they tell the patients they can do no more for them. The practice of syringing ears without first making ocular inspection—by aid of the speculum and mirror—is most unscientific, useless in many cases, and always fraught with danger.

A case of tinnitus, caused by pressure of a small piece of wax against the drum, came under my care. After inspection by means of the speculum and mirror, a few syringefuls of water removed the trouble. This man told me that he had been treated for a long time by two physicians, who prescribed various internal remedies. Any one who had seen the marked effect of Politzer's method of inflating the drum will make himself master of it, and use it, if he has the welfare of his patients at heart.

It is not a very difficult matter to pass the Eustachian catheter. It is much more difficult to diagnose the exact state of the middle ear and Eustachian tube by its aid. Every medical man ought to be able to pass the catheter. The following circumstances may occur at any time to any practitioner:—One of his patients among the better classes may get catarrh of the middle ear accompanied by tinnitus. After a preliminary consultation with his medical adviser, the patient takes a journey to a specialist. The catheter is used, and found to be of service. The patient wants to get home again, and the specialist advises that the catheter be passed twice a week for a time. It now falls to the lot of the regular medical attendant to carry out this instruction. If he does not possess the requisite knowledge and skill, I do not envy his position. This is no imaginary case at all, for it is only a description of a case that came under my own care. On one occasion I passed the Eustachian catheter, and, on inflation, distinctly, but feebly, heard the air impinging against the membrana tympani by means of the otoscope. I withdrew the catheter and re-introduced it, and then heard with and without the aid of the otoscope a very loud perforation sound. The state of the Eustachian tube, middle ear, and membrana tympani, and also the way in which the end of the catheter is introduced influence the sound produced. In the case just mentioned, tinnitus was chiefly complained of. The patient said to me after the inflation, "The tune of the singing is changed." The singing was not so loud as it was before the use of the catheter.

Two cases came under notice in which it was impossible to see the membrana tympani owing to the presence of a large number of hairs. When cases of this kind occur the medical man ought to try to get a view of the drum-head by oiling well the meatus. If this fails the hair ought to be cut by a very fine scissors.

Many cases are benefited by keeping the external meatus clean (such as cases of chronic catarrh, and of exostosis); other cases where the drum is perforated are benefited by cleansing the external meatus, middle ear, and Eustachian tube by warm water. This can be done by any practitioner.

In the above paper I have shown that great success will often follow very simple treatment in ophthalmic and aural cases. I have dwelt on the mistakes made by neglect of these simple matters which came under my own observation. If this paper succeeds in any degree in popularising ophthalmic and aural work among general practitioners, I shall be more than satisfied.

MM. ARLOING, Cornevin, and Thomas have proved that if a cow is inoculated against anthrax during gestation, her calf obtains immunity against the disease.

A HOLIDAY TOUR IN THE ARDENNES.

[FROM A CORRESPONDENT.]

Spa, July 12, 1882.

At this season, and during the coming months, overworked practitioners will be taking their annual holidays. Many will be puzzled in selecting a route which will not only meet their wants pecuniarily, but also supply change of air and scene, so that they may return refreshed to the arduous work of general practice.

A short description of a tour in the Ardennes may not prove uninteresting to my fellow readers of the *Medical Press and Circular*. Tempted by "A Trip to the Ardennes," referred to in your issue of June 14, I selected my this year's holiday on the banks of the Meuse, the Valley of the Vesdre, and the Ardennes. This included a visit to the following towns:—London, Harwich, Antwerp, Brussels, Namur, Dinant, Huy, Liège, Pepinster, Spa; returning by Verviers, Liège, Louvain, Malines, Antwerp, Harwich, London, the cost of a thirty days' return second class ticket, saloon steamer, being only £2 9s. 7d. by the Great Eastern Railway Company: Starting from Liverpool Street Station at 7.10 p.m. Harwich was reached at 9 p.m., where an excellent boat, the *Prince of Wales*, was in waiting alongside the train, for the voyage to Antwerp. The berths were exceedingly comfortable, stewards attentive, charges for breakfast, refreshments, &c., moderate. Antwerp was reached about 10.30, after a pleasant passage, in time to catch the 10.55 train to Brussels. Antwerp affords considerable attractions, which may be found in all the guide-books, as, for instance, its cathedral, picture galleries, &c. Travelling thus, Biedeker's "Guide to Belgium" will be found very useful. Custom House officers come on board at Antwerp to examine all luggage, so that the tourist should not take anything contraband. On the return the examination of luggage at Harwich is much more stringent than in the outward journey. A passport is not necessary.

After seeing the sights of Antwerp, we went on to Brussels, which is well-known as being a miniature of Paris. For those who speak French it is cheaper to obtain apartments, and we were able to secure excellent ones in the Boulevard Anspach, at the corner of Rue du Marche aux Poulets. Bed-rooms here vary from three to six francs per night. Breakfasts, dinners, and luncheons, &c., can be had at the cafés, in which Brussels abounds, prices varying according to class of café. We dined at the Grand Restaurant du Rocher de Cancale, and as a specimen of an elaborate, yet ridiculously cheap, meal, I give the following *menu* of a three franc dinner:—1. Julienne soup; 2. Oyster patties; 3. Fish and potatoes; 4. Beef steak and celery; 5. Veal and tomatoes; 6. Fowl and salad; 7. Ecceisses; 8. Sweets; 9. Dessert, strawberries, raspberries, &c. Wine may be obtained at all prices. The guide-books describe all the places of interest worth seeing. Brussels will afford amusement to the visitor for at least four days. There is one place not mentioned in some of the books, viz., "La Musée du Nord," where a pleasant and instructive evening may be spent. There is a small theatre, an excellent band, and many interesting objects to be seen, and games to be played.

A visit to the University may of course be made, but at present the classes are over, and it is deserted, except by the officials. Brussels University has thrown open its doors to English practitioners on very liberal terms. The M.D. Brussels may be obtained, by an examination conducted in English, on payment of £22 (550f.). The secretary informed me that seventeen English practitioners had passed in June, so that the University has been enriched during that month to the sum of £374. It is evident there is some want in our English system of qualification when this sum is given to a foreign University for the diploma of M.D. Practitioners are evidently anxious to possess the degree of M.D.; and this arises from the fact that many students take out licenses from the different Colleges of Physicians, and find in after-life they have made a mistake, as these licenses do not entitle them to be called doctors. It would be better to meet this want. If some of our English Universities would throw open their examinations to qualified practitioners in medicine, they would do a service to those who possess only licenses in medicine; otherwise, in a short time England will be flooded with Belgian M.D.'s. Durham is open on condition that the practitioner should be forty years of age, and fifteen years in practice. I fail to see the reasons for these restrictions.

Mais revenons à nos moutons. From Brussels, starting from the station, Quartier Leopold, the railway takes the tourist through a lovely country to the little town of Dinant, where the "Jete d'Or" may be selected as a place of residence for at least a week for excursion into the Ardennes. There is a recognised tariff of 7½*s.* for a day. This includes bed, breakfast, dinner, and supper. At this price the English travellers may think the living cannot be very good. The menu for July 2 is a sample of an ordinary dinner. Menu—1. Potage vermicelle; 2. Saumon à la Hollandaise; 3. Filet de bœuf, Endives; 4. Tete de veau Mayonnaise; 5. Poulardes rôties, petits pois; 6. Jambon à l'Ardenne; 7. Salade; 8. Frais, dessert. This hotel is well-known, and deserves the reputation it has obtained. Its picturesque position, its grand background of rocks, up which the visitors can ascend by a winding pathway cut in the rock, reaching the grand plateau at the top, from which an unequalled view may be obtained of the old town of Dinant and the lovely country surrounding it will not be readily forgotten. The descent may be made through the caves in the rocks, in which this part of Belgium abounds—viz., the "Grotto of Mont Zal." Geologists will be very much interested in this Grotto, as it is one of Nature's curious freaks. It is not so large as the Grotto of Han, or that of Rochefort, which may be visited later on in the journey. From Dinant numerous excursions may be made either on foot or in carriages. Guide-books afford all necessary details as to places of interest.

Leaving Dinant, the better plan is to sacrifice the railway ticket, and return to Namur by boat (1*l.* 65 cents.). After a short stay at Namur, Spa should be made headquarters for a week if possible. Spa has been, at one time, a favourite English resort. In the old gambling days many thousands were lost and won by our old English bloods at its famous gaming tables. But all things are changed; Monaco has taken the place of Spa. At the present day it is a favourite resort of English people and Parisians, who come to drink the waters and take the baths. It is a charming place in which to rest. Nestling among its tree-clad hills, with its promenades, avenues, and parks, Spa at once impresses the visitor. There are a number of hotels at which the tourist may take up his abode, and he can live either at an expensive or at an inexpensive rate. Apartments may be obtained from 3*s.* a day; dinners from 3*s.* We secured an excellent bedroom and salon, with use of piano, &c., at Pavillon Royale, close to the station (W. Carozzy), at 5*s.* a day. The ordinary daily routine consists of promenades to the pump room, where the waters may be drunk; the park, where bands play twice a day; the casino for dancing, &c., may be visited later in the evening—theatre, &c. Excursions may be made to neighbouring places, which will be found fully described in the ordinary guide-books.

The mineral waters of Spa are highly recommended for anemia, chlorosis, affections of the urinary organs, sterility; and the baths are said to be particularly effective in neuralgia, paralytic, rheumatic, gouty, and all nervous diseases. The season opens 1st May, and finishes 31st October. The air is mild, pure, and refreshing, so that anyone requiring perfect rest could not select a better place for a sojourn of three weeks or a month. I must defer to another letter a description of other portions of the tour. I have said enough to show that, at a very moderate expenditure, a beautiful portion of the Continent may be visited; a portion too little known, and not sufficiently appreciated, by English tourists.

The Great Eastern Railway, by their liberal arrangements, seem to me to deserve encouragement, and it is to be hoped that many will avail themselves of the coupons issued by the Company. It seems almost incredible that for £2 9*s.* 7*d.* the Company can afford a tour of this length, which will include a visit to the old town of Antwerp, to gay Brussels, busy Namur, quaint Dinant, peaceful Spa, &c. We are thus introduced to all the phases and peculiarities of Belgium life. We are enabled to tread historic ground, places famous in story, finding ourselves at one time amongst people primitive in their habits, and at another amongst those of a more advanced luxurious civilisation. The traveller need not encounter extortionate hotel proprietors, nor be extravagant unless he desires it. He can ascertain the daily cost of expenses. The Belgians do not seem to think that every Englishman is a millionaire whose pockets are to be freely bled. As an Englishman he will be treated with every courtesy, and should return from his journey impressed with the simplicity of the manners of the small nation which possesses such a

beautiful country, and seem to enjoy life in a manner not sufficiently appreciated in the fierce competition which is taking place in Great Britain.

(To be continued.)

Clinical Records.

CASE OF POISONING BY OXALIC ACID—RECOVERY.

Under the care of ROBERT GRAY, L.R.C.P.E., L.R.C.S.I., Armagh.

ON Thursday evening, the 29th ult., at 7 o'clock, p.m., I was called upon to visit a woman, æt. 30, who, the messenger said, had taken poison; on reaching her residence I learned the following particulars:—About 2 o'clock p.m., she sent her brother, a half-witted creature, to a druggist's for a pennyworth of citrate of magnesia, but he asked for a pennyworth of oxalic acid, which was supplied to him, this he brought home and handed to her, she, without looking at the label opened the package, poured the contents into her hand, and put the greater portion of it into her mouth, chewed and swallowed it, the remainder she put into some water, shook it about, and then drank it. Almost immediately, she felt a burning sensation in her mouth and throat, vomiting set in, and continued without cessation, even a spoonful of water would not be retained on her stomach. Up to the time of my visit at 7 o'clock, she thought it would not do her any harm, and therefore allowed nearly five hours to elapse before sending for me. At this time, she was very prostrate, with, as she said, a dreadful sense of sinking, severe cramps in the muscles of the extremities, pulse very feeble and slow, mucous membrane of cheeks and gums appeared as if it had been rubbed with nitrate of silver, great pain in epigastric region, which was tender on pressure.

I administered opiates, limewater and milk, and demulcents, applying externally hot poultices over abdomen, and hot water jars to feet.

At 10 o'clock, p.m., no remission of symptoms, but towards morning she experienced slight relief from vomiting and cramps, symptoms of enteritis now manifested themselves, but soon yielded to treatment, and on Saturday, she appeared to have entirely escaped from all danger consequent on the primary or secondary effects of the poison.

On inquiry at the druggist's, I learned that the quantity of oxalic acid given to her brother was half an ounce, the whole of which she must have swallowed, except a few grains, about five grains, which were given to me for examination, that had remained in the package.

I have since learned that before taking the acid, this woman had taken whisky enough to muddle her, so that she did not discover the difference in her mouth between the acid and citrate of magnesia. Might the stimulant have prevented the well-known depressing effect of oxalic acid proving fatal?

France.

[FROM OUR SPECIAL CORRESPONDENT.]

HYDROPHOBIA.—At the Académie de Médecine M. Dumont related the case of a shepherd, aged 38, who was brought to the Hotel Dieu, Caen, suffering from hydrophobia. This man was bitten on the 16th April, or five weeks before, by a mad dog. A woman who was bitten by the same animal died thirty-three days afterwards of hydrophobia. The news of her death affected him very much, and on the 22nd May he was seized with extraordinary thirst and with difficulty in swallowing. The dysphagia becoming accentuated, he got greatly excited, and manifested the desire to bite those around him, but he was strongly bound and brought to the hospital. During the journey he lacerated his own hand in a horrible manner with his teeth. On examination it was proved that there could be no doubt as to the diagnosis, which was hydrophobia. He asked

frequently for drink, and as he filled his mouth with the liquid, he rejected it again. He complained of a weight in the chest, great pain in the throat, and asked to be killed. The treatment consisted of bromide of potassium, two drachms in the twenty-four hours, syrup of codeine, chloral, &c., and subcutaneous injection of nitrate of pilocarpine, at first three times a day, afterwards only twice. Under the influence of this treatment the agitation disappeared, the dysphagia ceased, and the appetite returned, and at the end of a fortnight the cure could be pronounced complete. The author of the communication attributed the happy result to the pilocarpine. M. Bouley reported another case of hydrophobia treated successfully also by a friend of his in the country. The treatment consisted in the hundredth part of a grain of arsenite of strychnine and the same dose of hyoscyamus with the fifth of a grain of the monobromide of camphor, given all together, every ten minutes, and at the end of half-an-hour injections of pilocarpine were made, and the patient was enclosed as far as the neck in a sort of a case heated with candles and a spirit lamp. Sixty injections in all were given, and the patient was left in the hot-air bath twenty-four hours, and during the course of five days. At the end of this time all the symptoms had disappeared, and the treatment was suspended. M. Germain Sée made a communication relative to the employment of pilocarpine in different diseases, especially in diphtheria, puerperal eclampsia, Bright's disease, and hydrophobia. In all these cases, said M. Sée, this substance was absolutely ineffectual. As to hydrophobia, he had a case last November. The individual, aged twenty-four, was bitten in the eyebrow six weeks before. The disease was well pronounced. He treated him by injections of pilocarpine (two-fifths of a grain each time) at eleven in the morning, at four and six in the evening. There was abundant salivation, but that was all. The patient died next day. M. Beaumetz said that out of a total of 28 cases of hydrophobia treated last year, six were treated with pilocarpine without any favourable result.

PHENIC ACID IN THE TREATMENT OF TYPHOID FEVER.—At the Société Médicale des Hôpitaux a memoir was read on the antipyretic action of phenic acid in enema for the treatment of typhoid fever. M. Damaschino replying to the author, considered that the action of phenicated enemas was often very energetic, and sometimes, especially when they are retained, produces toxic effects, such as dark-coloured urine, cerebral disturbance, and pulmonary congestion; the temperature was frequently considerably lowered. M. Lireday hitherto ordered a great many phenicated enemas, but from the grave accidents that he observed he considered that it was a very dangerous treatment, and he renounced it altogether, unless when disinfection of the contents of the intestine is indicated, and then on the understanding that the enema be not retained a moment. M. Labbé, in giving the result of his experience, declared that he had always obtained good effects when the antiseptic was used with moderation. M. Ferrand showed himself very favourably disposed towards the employment of the agent in question in the treatment of typhoid; it rendered him good service both in this disease and in acute tuberculosis. The anti-febrile action of phenic acid appeared to him to be proved beyond all doubt.

ANTI-ASTHMATIC PREPARATION.—Dr. Huchard, of the Hôpital Zenon, employs the following mixture in the treatment of asthmatic patients subject to bronchial catarrh:—Iodide of potassium, 3iiss; tincture of lobelia, tincture of

polygala, of each 3iiss; extract of opium, 2 grs.; water, 3x. A tablespoonful morning and evening.

TREATMENT OF CORYZA BY SULPHATE OF ATROPINE.—Believing that the action of atropine on the nasal mucous membrane consisted in the decrease of the secretion and even in the drying up of the membrane completely, Dr. Gentilhomme, of Reims, employed this agent in the treatment of coryza. He had a patient very subject to this disease, to whom he ordered one-hundredth of a grain of sulphate of atropine in pill, to be taken at the first symptoms of the disease. A quarter of an hour after the first dose all sneezing had ceased, the secretion stopped, and respiration became free as before. The same phenomenon reproduced itself several times in this patient. The attacks diminished under the influence of the atropine, and eventually disappeared. Another case was that of an old man who for thirty years was subject to coryza continually, and was cured equally by this remedy. When bronchitis exists at the same time as the coryza, the atropine produces a favourable effect also on the bronchial mucous membrane of which it modifies the secretion, and diminishes the duration of the disease. It will be remembered that in the codiculative sweats of phthisis the sulphate of atropine in pills at the dose of 1-50th of a grain is the accepted remedy.

Hospital, Physician to the Hospital for Diseases of the
Throat, &c.

(Continued from page 27.)

THERAPEUTICS OF SULPHUR WATERS.

THE sickening smell of these waters is due to the sulphuretted hydrogen they give off, and to this gas has often been attributed their remedial efficacy. It has been shown, however, that the alkaline sulphides slowly evolve the same gas, and the waters which contain these bodies may claim to have the therapeutical value lately assigned to calcium sulphide. However doubtful may be the influence of medicinal doses of this salt, the waters which contain it have long held the highest place among sulphuretted waters, and their history is full of marvellous cures. Whether their future records will be as satisfactory, or whether their action will be more carefully studied, remains to be seen. Certain it is that a large number of able observers have lost faith in the majority of sulphur springs, and others have held that their effects are to be accounted for by their other constituents, or by the effect of baths, climate, and the complete change involved in a visit to the spas. On the other hand, it is held by many that the sulphur compound is the essential ingredient, and that it possesses extraordinary therapeutical powers. In German medicine abdominal plethora plays an important part, and sulphur waters are believed to control this

condition and to remove the "hæmorrhoidal diathesis." The largest group of sulphur baths is that of the Pyrenees, on the French side of which only there are 110 distinct resorts with about 500 springs.

The poisonous effects of sulphuretted hydrogen are well known, but are never observed from drinking the waters which are richest in the gas, although it is said that inhalation over the springs has to a very slight degree produced toxic symptoms. The favourite theory in Germany is that when the water is drunk the sulphuretted hydrogen passes directly into the blood of the portal vein, and there hastens the destruction of partly-used blood corpuscles by abstracting the iron. Thus the anæmia that succeeds full courses is accounted for as well as the blackening of the fæces which is constantly observed. Of course when iron is present in the water the last remark would not apply; but, when there is none, sulphide of iron has been found in the dark evacuations, and anæmia has been so marked as to render a course of chalybeates necessary. At the same time enlargement of the liver is decreased, and the symptoms of sluggish portal circulation disappear. Thus a considerable number of indications are explained, and in the same way the use of the waters in metallic poisoning is placed on a better foundation, for the liver is the part where the metals are mostly deposited, and the old notion of direct combination of metals and sulphur in the system was unsatisfactory, since most of the sulphides are insoluble.

It has been supposed that the alkaline sulphides are only effectual by liberating the gas in the system; but much may be said against this view. Recently there has been a disposition to attach greater importance to these sulphides, and although the gas is frequently present in the intestinal canal it seems never to be absorbed. It is then scarcely to be expected that additional traces introduced into the stomach produce all the curative influence of the mineral waters containing them, while in cases of poisoning by sulphide of potassium the smell of sulphuretted hydrogen has been noticed in the breath. When prolonged baths are taken some of the escaping gas is necessarily inhaled, but the quantity must be small, or the effects would more frequently be observed. Sometimes, however, inhalations are systematically employed.

For drinking, the cold springs are at least as efficacious as the hot. Indeed, some of the most highly-charged waters are cold. They are reputed, in small doses, to increase the secretions of the alimentary canal. Some are aperient, others not. Most seem to stimulate tissue metamorphoses, and so reduce obesity, as well as abnormal swellings. Some exercise thus their chief effect on the chylipoietic viscera. Others act more on the skin. And others, again, claim to have a beneficial influence in diseases of the respiratory organs. No doubt all increase the action of the skin and kidneys.

We will now pass in review the therapeutics of those waters of which the chemical characters have been described in preceding reports.

Harrogate.—Situated on a table-land rising from 300 to 400 feet above the sea-level, this famous resort has the advantage of a dry bracing climate, though it is rather cold in winter. There are good pump-rooms, and also excellent bath establishments. A visit to Harrogate is

often more effectual than a season at a Continental spa. But it is with the water for drinking we have to do. It keeps well, and is, therefore, adapted for bottling. There are numerous springs, but only a few are utilised. Sulphide of sodium and sulphuretted hydrogen are both found in the waters. They are associated with so much chloride of sodium that Harrogate may be fitly compared with salt spas. The waters, therefore, do not constipate—on the contrary, they are aperient. Moreover, they are not so likely to induce anæmia. Patients sometimes take them for a long time with distinct benefit. They seem to stimulate the abdominal viscera and promote tissue change. Dr. Myrtle thinks the aperient action less lowering than that of saline purgatives. From one to three weeks is the period for a course, but many have taken it much longer. It requires a pint to a pint and a-half to act as a purgative, and this is divided into three doses taken at intervals of a quarter or half-an-hour before breakfast. As an alternative, 2 to 8 ounces three times a day. As the sulphide of sodium amounts to 9·10ths of a grain per half-pint in the stronger springs, it will be seen that this substance is taken in appreciable doses. But with the sulphide the patient takes 63 grains (per half-pint) of solids, $4\frac{1}{2}$ being distinct purgatives, and $2\frac{1}{2}$ salines. If the stomach is delicate the waters may be warmed. Harrogate is useful in dyspepsia and defective assimilation, as well as in functional disorders of the liver and abdominal congestions. Nervous affections, metallic poisonings, and syphilis are also said to be benefited. Skin diseases also form an important contingent of the cases treated at Harrogate with as much success as at any sulphur spa. The chalybeate waters of Harrogate have already been mentioned. The presence of the two gives the place a prominent position. The bottled waters may be taken as at the springs, either cold or warm, for two or three weeks, according to the indications; but Harrogate is so accessible to our readers, and has such a tonic bracing climate, that it may more often be resorted to for a holiday by the invalids who need to try its waters.

Aix-la-Chapelle has not the attractions of Harrogate; it is, indeed, a dirty manufacturing town, and even the country around is not inviting. But its bathing establishments are very fine, and it may be regarded as the representative Spa of Germany. Hot baths, douches, and vapour baths are used, and the water is also drunk, but the great reliance is on the baths. All the elements of the thermal system, so much recommended in rheumatism, gout, and abdominal disorders, are combined at Aix. Scrofula and skin disorders are also treated here, and the place has been much exploited for syphilis, but in this disease iodide of potassium or mercurial inunction is always employed in conjunction with the baths, so that if the doctors have great faith in the waters they are also fully convinced of the power of these drugs. The waters are also employed in metallic poisoning, and even so judicious a writer as Dr. Lersch, who has been called "the father of balneology," expresses himself as satisfied that they are efficacious in improving the health of those who have suffered from the effects of mercury, and that they also tend to make latent syphilis manifest itself. The water is not nearly so much mineralised as that of Harro-

gate; it contains only $17\frac{1}{2}$ grains in the half-pint, only 0.04 gr. being sulphides.

Barèges, over 4,000 feet above the sea-level, offers a true mountain air, but the weather is very variable, and often too keen. It is in high repute for persons suffering from old wounds and for paralytics. In rheumatism, neuralgia, and bone diseases the baths are also recommended. The accommodation is poor, and there are no attractions, save the waters, which are suitable for bottling, as the sulphurisation is due to sulphides (4-10ths gr. per half-pint).

Eaux-Bonnes, situated lower down, 2,300 feet above the sea-level, offers a less trying climate with better accommodation. There is, however, considerable variation of temperature, and visitors should be warmly clad. It is most frequented for throat and lung affections, and, besides the baths, there are inhaling-rooms. But the mineralisation of the water is so slight that its effects have long been attributed to some undiscovered cause, and some of the local physicians do not hesitate to give the climate most of the credit. One can readily suppose that benefit may accrue from mountain air combined with change of scenery, occupation, diet, and regimen. Certainly chemistry reveals nothing to account for the beneficial effects so long attributed to this Spa. The water is not adapted for bottling.

Cauterets is 3,200 feet above the sea, and though the climate is rather variable it is in high repute for chronic bronchitis. Drinking the water is here in vogue, and it contains sulphide of sodium, but not more than 0.10 gr. in the half-pint. Some have supposed that the effect may be partly due to silica.

Bagnère de Luchon being only 2,000 feet above the sea has a much milder climate. It is rather changeable, but in the season fine weather may be expected. The bath establishments and other accommodation are far superior to those of the other Pyrenean Spas, and the waters are richer in mineral ingredients. The same cases are treated as at Barèges and Cauterets, in addition to which skin affections are said to be more benefited here.

SPECIAL WATERS.

The following waters contain iodine or bromine in minute quantities, and to these ingredients has sometimes been attributed the value of the waters:—

Kreuznach is usually classed with salt waters, and is celebrated for scrofula.

Luhatschowitz is a strong alkaline Spa.

Tepitz is an indifferent water.

Woodhall is a very strong salt water with an unusual amount of iodine.

GENERAL MEDICAL COUNCIL.

TENTH DAY, FRIDAY, JULY 7.

REGISTRATION OF MIDWIVES.

MR. MARSHALL moved the adoption of the report of the committee on the Draft Bill for the Registration of Midwives in England and Wales. He said it ought to be remembered that the credit of the measure was mainly due to Mr. Simons' action and the proceedings of the Council in the year 1877. The Committee had carefully considered how far the Council should accept responsibility under the Act. It was deemed desirable that the responsibility of appointing a Midwifery Board and of controlling the practice of women licensed under it should be accepted; any other course would be un-

becoming the importance of the Council. Should the Council now refuse its responsibilities, they might be forced on it by future legislation, and it would be best for the Council to face the duty boldly, and so remove all chance of local difficulties likely to arise if local authorities were permitted to be appointed by other agency than that of the Council. Mr. Marshall explained that the Branch Council in England was the body interested in the matter. The money objections had been removed by the decisions of the Committee to the effect that no expense should be incurred by the Council in the matter.

Rev. Dr. HAUGHTON seconded the motion. He had consented to the omission of Ireland from the operation of the Bill, his objections having disappeared before the clause admitting midwives to the Register without examination. The cumbersome machinery recommended by the Draft Bill was modified in committee. The fact that 60 per cent. of labours were attended by midwives was so important a fact that the Committee felt all differences should fade before it; and he cordially adopted the whole report.

Mr. SIMON referred to the fact that Sir Wm. Gull and himself had served on a Committee which had considered this subject formerly. He did not agree with all Mr. Marshall had said—not to the whole report of the Committee—though accepting much. The Council was indebted to the Committee, but their labour could hardly lead to any great result, because of the time at which its decision had been arrived at. It would have been more serviceable had the Committee dealt with principles rather than the details of an amateur Bill. Such a course would have been of greater public interest. The experience afforded by the consequences of proceeding along the lines of an amateur Bill was of an ill kind in connection with the Dentists' Bill. Similar disasters would follow similar action in regard to the Midwives' Bill. Until the Bill was introduced as a Government measure it could not be effectively considered. He fully admitted the importance of the matter, and the eminence of its promoters. If the report was accepted the Council must resolve itself into Committee on it. To avoid this he recommended acceptance of only those resolutions of the Committee which dealt with principles. The Committee had not appreciated the gravity of their own proposals, and on the question of money they were not accurately informed. The Council could not evade all responsibility of this kind; and in case of disagreement between it and the proposed board, it had no means of continuing its functions under the Act as proposed. The Council should accept a permissive position; it might sanction the appointments of boards, &c., but it was no part of its duty to undertake to make them. The right course to pursue would be for the Committee to approve the principles of a Bill, and act by sanctioning, rather than originating, a measure. Local registers, and not a central register, would be required, and much simpler machinery than that recommended by the Committee. The difficulties found in dealing with dentists would be much increased when dealing with midwives.

Sir WM. GULL asked what would be the Council in the absence of Universities, medical authorities, or schools, for this was its position regarding midwives.

Dr. QUAIN declined to be called the promoter of the Dentists' Bill. He had always advised the Council to have nothing to do with Bills. He was unable to see how Mr. Simon could speak as he had. No result had followed from the former actions of Mr. Simon and Sir Wm. Gull. Nothing more simple could be suggested than for the Council to nominate a board to prepare a scheme, and receive a report from them periodically, as was provided in the Draft Bill. No responsibility would be accepted under it, and the Council would, in reality, be only the advisers of the Privy Council. He could conceive no more appropriate function for the Council than that allotted to it in the bill.

Mr. TURNER objected to the report being taken as a whole.

Mr. MARSHALL then moved, in place of the original motion, that the sections of the Bill should be taken in order.

Rev. Dr. HAUGHTON seconded the motion, which was carried.

A long discussion then ensued in Committee of the whole Council on each clause of the report presented by the Committee appointed to consider the Bill. During it, Mr. Simon made two or three very lengthy speeches in support of the objections he raised against the Council's acting on the sugges-

tions laid before it. He finally moved the following amendment, which Sir Wm. Gull seconded:—"That, as regards the proposals made in the Draft Bill to assign certain functions and duties to this Council, the Council is not prepared to accept the responsibility in unconditional and obligatory terms, such as are used in Clause 4 of the Draft Bill; but that the Council would not object to be made, under permissive law, the sanctioning medical authority in the proposed matter: with duty, in that capacity, to approve or disapprove any scheme which the Obstetrical Society (or others) might bring before it for such purposes as are in question."

The amendment was negatived.

At a later period of the debate, Prof. HUMPHRY delivered an emphatic and convincing speech in support of the proposals made by the Committee, and urged that the Council's duty was to initiate a measure, and not to consider merely principles further. It had considered principles, and uttered a decision on them long ago; Government could look to no other body than the Council to initiate a bill of the kind, as shown by its referring the Draft for its consideration. Mr. Simon was mistaken in his views of the responsibilities which the Council would incur under the Bill. It would only create and regulate the action of a midwifery board. Its responsibility would be transferred to the Privy Council, inasmuch as appeal would be to the latter, and not to the Medical Council. Finally, after suspension of the standing orders to enable the business before it to be concluded, the Council having resumed, it was moved by Mr. MARSHALL, and seconded by the Rev. Dr. HAUGHTON, and agreed to:—

"That the following report of the Council in committee on the draft bill for the registration of midwives in England and Wales be received, adopted, and entered on the Minutes:—

"A. That, in view of the absence of any complete and satisfactory provision for the proper training and due qualification of the women who now act as midwives amongst the poorer classes of the community in England and Wales, it is—as expressed in a resolution of the Council, agreed to on the 24th May, 1877 (Minutes, vol. xiv., p. 198, clause 15), and communicated forthwith to the Lord President of Her Majesty's Privy Council—desirable to provide by legislation for the following two objects: First, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and, secondly, that the lives of women in labour should, as far as practicable, be protected from the incompetent.

"B. That, for the attainment of these objects, the essential conditions of any legislative enactment are the due training, examination, certification, and registration of a class of qualified midwives, subject to this further condition, that women now practising as midwives may, if certified to be of good character, and to possess a competent knowledge and experience, be granted certificates under the enactment and be placed upon the Register.

"C. That, whilst all registered midwives should be entitled to certain privileges, they must also be subject to supervision and control.

"D. That, though agreeing with the limitation of the proposed enactment for the Registration of Midwives, in the first instance, to England and Wales (Sect. 2), the Committee does not see any objection to the subsequent extension of legislation for a similar purpose to Scotland and Ireland.

"E. That it may be made competent to the General Medical Council to delegate to the English Branch Council any functions and duties which, under the Draft Bill, are proposed to be assigned to it, except that of making representations to the Privy Council.

"That these functions and duties be as follows:—(a) The appointment of a Midwifery Board and its maintenance by the filling up of vacancies (Sect. 4); (b) the reception of an annual report from the Midwifery Board as to money received and expended, as to the proceedings of the Board, and as to any suggestions made by the Board (Sect. 5); (c) the power to request or demand information from the Board (Sect. 5); (d) the duty of transmitting the annual report of that Board, with comments approving or disapproving it, to the Privy Council (Sect. 5); (e) the duty of receiving from the Privy Council the examination rules framed by the Midwifery Board, and giving an opinion to the Privy Council upon them; (f) that of receiving notices of and commenting on any modifications made in these rules by the Privy Council (Sect. 18); and, lastly (g) that of giving an opinion to the

Privy Council on the scheme for regulating the duties and practice of registered midwives' (Sect. 28).

"F. That, as regards the proposition made in the Draft Bill, that any of the funds at the disposal of this Council, or of any Branch Council, might be devoted to the purposes of an enactment to secure the registration of midwives, the Council is of opinion that this is undesirable, and that such portion of Section 34 as relates to those funds should be omitted from the Bill.

"G. That the Council, whilst offering no opinion as to the appropriate time for legislating on this subject, recommends that, in the event of a Bill being brought before Parliament, a copy of the measure, and notice of changes in it, should be communicated to the Council.

"H. That the suggestions of the Committee in Section 3 of the Report, and other proposals contained in the Draft Bill, be forwarded to the Privy Council as opinions of the Committee."

The Council then adjourned.

ELEVENTH DAY, SATURDAY, JULY 8.

On the motion of Mr. MARSHALL, seconded by Dr. HAUGHTON, the report on the Draft Bill for the Registration of Midwives in England and Wales, adopted by the Council yesterday, was ordered to be transmitted to the Lord President of the Privy Council, together with the minutes of the Council.

Dr. SMITH's motion "That the Visitation of Examinations in the Universities be postponed until the year 1883" was, after a short conversation withdrawn.

CASE OF PERSONATION.

On the motion of Mr. MACNAMARA, seconded by Dr. HAUGHTON, a resolution was agreed to, calling the attention of the Executive Committee to the case of a medical student who was summoned at the Dublin Police Court for seeking to bribe a London practitioner to personate him, and pass his examination for him.

THE DEARTH OF SUBJECTS FOR DISSECTION.

Dr. LYONS moved, "That a committee be appointed to inquire into and report upon the deficiency of subjects for anatomical and surgical teaching and examinations, and to suggest such remedies as they may deem expedient." He said the Council was agreed that it was essential that students should be examined on the dead subject, but there seemed to be a difficulty about obtaining the bodies. It had occurred to him that perhaps the horse and the ox might be utilised. In that way, indirectly, a good deal of comparative anatomy would be acquired by the majority of the profession, and this would lead to a more humane treatment of the lower animals. Mistakes of the most frightful kind were common in the practice of farriers and others, and a vast amount of cruelty was unnecessarily caused when the intention was only to do good. The committee might also consider how far it was possible to establish an interchange of dead subjects between one portion of the kingdom and another.

Dr. PYLE seconded the motion, which was agreed to.

Mr. Turner, Mr. Marshall, Dr. Humphry, Dr. Fergus, Dr. Pyle, Dr. Heron Watson, Mr. Macnamara, Dr. Haughton, and Dr. Lyons (chairman) being appointed a committee for the purpose.

THE UNIVERSITY OF DURHAM.

Dr. STORRAR then moved, "That the Registrar of the Medical Council be instructed to address a letter to the Registrar of the University of Durham, suggesting for the consideration of the university whether the time has not arrived when it is expedient for the university to discontinue their 'registration examination for medical students.'" He said that great exertions had been made by the Council from time to time to bring all the examinations in Arts under boards for general education, and do away with Arts examinations of a special character. When these examinations were first instituted, the University of Durham, seemingly with a view to meet the demands of the time, established a special examination for medical students. It was not, in the proper sense of the word, a university examination that led up to any degree. Men from any part of the United Kingdom might attend it, pass, and then go off to any other school. There was really no necessity for it, and therefore he thought the Council should ask the university whether the time had not come for abolishing it altogether.

Dr. PYLE seconded the motion. There would not be a Senate meeting till October, but he would bring the subject before them on that occasion. He believed that the examination had been a very good one lately, but the inquiry was a proper one to make.

The resolution was agreed to.

UNQUALIFIED PRACTICE.

Dr. QUAIN moved, "That it be remitted to the President of the Council to bring under the notice of the Registrar-General the case of G. H. Griffin, an unqualified person, who in certain death certificates forged the name of a registered practitioner named D. B. Murdoch." He said that in 1877, when a somewhat similar case arose, the Registrar-General assured the Council that, if a clear case were reported to him of an unqualified medical man forging, for his own purpose, the name of a registered practitioner, he would take opinion of the legal authorities serving under the Lords of the Treasury as to whether proceedings should not be instituted. There never was a clearer case than the present, for Mr. Murdoch swore that he had not given Griffin any authority to sign his name.

This having been seconded by Dr. BANKS, was unanimously agreed to.

PRELIMINARY EXAMINATIONS, IRELAND.

Dr. STORRAR moved, "That the examinations of the Intermediate Education Board of Ireland—junior grade, middle grade, and senior grade—be placed in the list of examinations recognised by the Council, provided the certificates contain all the subjects required by the Council." These intermediate examinations, he said, were the outcome of Lord Cairns' Act for encouraging secondary education in Ireland, and they appeared to be of a very high character. The only reflection he had heard made upon them was that they were too high, but that was not a complaint that the Council would give much weight to. They were exceedingly desirous of doing away with all special examinations conducted by medical bodies, or under the superintendence of medical bodies. The only two bodies in Ireland which continued to superintend such examinations were the College of Surgeons and the Apothecaries' Hall, and it would greatly facilitate the discontinuance of those examinations if the intermediate examinations were recognised by the Council.

Dr. HAUGHTON seconded the motion.

Mr. COLLINS said the Apothecaries' Hall of Ireland was perfectly willing to transfer its preliminary examinations to the Intermediate Commissioners.

The resolution was agreed to.

EXAMINATION IN GENERAL EDUCATION.

Dr. STORRAR moved, "That the Registrar be instructed to address a letter to the following bodies:—The Apothecaries' Society of London, the Royal Colleges of Physicians and Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, the College of Surgeons of Ireland, and the Apothecaries' Hall, Ireland, calling their special attention to the following recommendation of the Council:—'It is desirable that the examinations in general education should be left to the universities and to such other bodies engaged in general education and examination as may from time to time be approved by this Council.' He was happy to say that the only body in England which now conducted its own preliminary examination was the Apothecaries' Society, while in Ireland there were only two bodies that did so—namely, the Apothecaries' Hall and the College of Surgeons. Thus the special examinations were both gradually got rid of.

Mr. SIMON having seconded the motion, it was agreed to.

FOREIGN AND COLONIAL EXAMINATIONS.

Dr. STORRAR moved a resolution instructing the Registrar to send a circular to each of the Indian, Colonial, and foreign universities and colleges asking for information on the following points with respect to their examinations recognised by the Council:—(1.) Percentage of highest marks; (2.) percentage of pass marks; (3.) number of candidates at examination referred to; (4.) copies of the examination papers set. He said that seventy-five universities and colleges were specified in the list, embracing the universities of India and British North America, some in the United States, one in the West Indies, some in Australia and New Zealand. The question was naturally asked, what was the value of those exami-

nations? and that was what they wanted, if possible, to find out. For himself, he had no positive suspicion that the Colonial examinations were a sham: from all he could learn, the authorities there had done their best to promote higher education in Arts.

Rev. Dr. HAUGHTON seconded the motion, and said that several of the bodies were not teaching bodies at all in the proper sense of the term. He had no knowledge whatever of the Arts examination of the Medical College of Michigan, for instance. He knew that the University of Michigan was a highly thriving and advanced university, and therefore it appeared odd that the university should not be on the list, while the college was. Again, the University of California, which was in a very weak condition, was on the list, while all the great universities of America were conspicuous by their absence. The reason given was that these latter bodies never asked to be put on because none of their students ever wanted to come here and register, but that excited a suspicion as to the reason why the other bodies wished to be on the Register.

Dr. FERGUS cordially supported the resolution, and reminded the Council that two years ago he drew attention to the same subject, and proposed several additions to the standing orders, which he was then told it was impossible for the Council to pass.

The PRESIDENT said there was a strong feeling on the part of the medical men of the United States to ally themselves with this country, and to send students here especially in connection with clinical study.

The resolution was agreed to.

DENTAL PRACTITIONERS.

The following report by the Dental Committee was then read:—"With reference to the cases of John Thomas Lambert and Joseph Walker, referred back to them by the General Council, the Committee find that John Thomas Lambert and Joseph Walker have now answered the communications addressed to them, and that they are in the same condition as regards qualification as other persons who are on the Dentists' Register, and who answered in due time the letters sent them by the Council. The Dental Committee report these facts to General Council."

On the motion of Dr. E. PITMAN, seconded by Dr. SMITH, the Council resolved:—"That the report of the Dental Committee not having put the Council in possession of evidence to show that John Thomas Lambert and Joseph Walker were not *bona fide* engaged in the practice of dentistry, the Council is not, therefore, prepared to order the removal of their names from the Dentists' Register."

Mr. TURNER moved, "That one year's *bona fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study." He said the resolution would bring the education for dental students into conformity with the arrangements for medical students.

Dr. WATSON seconded the motion, which was agreed to, as was also the following, moved by Mr. TURNER, seconded by Dr. WATSON:—"That the three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student; but no year of such mechanical instruction shall be counted as one of the four years of professional study unless taken after registration."

Sir WM. GULL then moved, "That any or all of the qualifications in Schedule A of the Medical Act be registrable in the Dentists' Register."

Dr. STORRAR seconded the motion.

This gave rise to considerable discussion, in which Drs. Haughton, Quain, Lyons, Banks, Smith, Humphry, Pitman, and Storrar, and Messrs. Turner, Macnamara, and Simon took part, the principal objection being that, if the various dental qualifications were to be registered, the Council would next be asked to register theological, sanitary, and other diplomas.

The motion was, however, eventually carried.

The remainder of the sitting was occupied with dental questions of little interest to the profession, and the session concluded with votes of thanks to Dr. Acland for presiding, to the chairman of the Business Committee, Dr. Pitman, and to the treasurers, Dr. Quain and Dr. Pitman.

The PRESIDENT, in returning thanks, expressed his high sense of the value of the Registrar's services, and in his own name and that of the Council tendered him their best thanks for the able and assiduous manner in which he had discharged the complicated duties of his office.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLIAMS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 19, 1882.

THE NEW EXAMINATION.

THE idea of a new examination to be passed by every candidate for the diploma of the Royal College of Surgeons of England has by this time been tolerably freely canvassed at most of the centres of education which will be affected by it. The reception given to it is by no means indicative of unanimous approval, and there was plainly evidence of disagreement amongst even the respondents to the invitation of the College to “confer” on the subject of the proposed examination and the mode of carrying it out. A careful review, however, of the whole matter in dispute, and comparison of the advantages enjoyed and to be enjoyed, will probably result in general acceptance of, at least, the principle involved, and ultimately of the scheme in detail.

The College of Surgeons is unquestionably entitled to frame what regulations it will for the guidance of those who seek to obtain the qualification it dispenses; but it is naturally desirable that its action should always meet with the approval of the teachers to whom the training of its candidates is left. In the present instance the change to be effected will throw on the teachers of anatomy and physiology a certain duty additional to that they already discharge. Not only will they be in future the instructors of the students who join their classes, but they will also become the arbiters of their fate in respect to immediate or deferred examination. Henceforth, under the new rules, it will rest with the teachers to decide whether men shall or

shall not be permitted to proceed for the “primary,” and no longer will they occupy the unsatisfactory position assigned to them by the “test” system. Hitherto the duty of “signing-up” has been an invidious and wearisome task; now will it become a pleasant and acceptable labour, inasmuch as every signature to a schedule will be the absolute sign of successful study on the part of the recipient, and a proof also of successful tuition on the part of the giver.

On the advantages that must follow on the institution of a *compulsory* examination of first year men, there can hardly be two opinions. Among medical students are to be found always a certain percentage of lazy men, whom none but the strongest incentives will move to work. So long as these men are not confronted with certain and unavoidable penalties of idleness they will continue to act on the principle of delay, and so long will there be of necessity, in every school, a hopeless residuum. When, however, such dilatory students are confronted with the necessity for passing an examination at the end of their first year of study, and are assured that without the proof of having done so they will be refused admission to a qualifying examination, they will be compelled to recognise the gravity of their position, and to work with a view to overcoming the difficulties before them.

In this way the new regulation will be productive of benefits that “tests” have been powerless to secure; and it will therefore be more effective for good. There are a few students at every school whom it would be well to prevent from incurring the risk of certain failure at the College, but who have it in their power at present, by complying with the letter of existing rules, to insist on being “signed up,” with a view to undergoing the ordeal. As things now are, the teacher, though morally convinced of the fruitlessness of such student’s efforts, is yet powerless to prevent him from proceeding with his vain attempt, being unable to withhold the statement of his pupil’s *diligent* prosecution of his studies. Armed, however, with authority to deter the ignorant from advancing further, a new and most effectual weapon is supplied to him, and his endeavours to send only competent candidates to examination at the College will no longer be rendered futile by the absence of absolute control over the proceedings of students.

Objections have been urged in many quarters against the proposed changes; in most instances, however, they are uttered by teachers of other subjects than those on which examination will take place, and it may fairly be questioned how far such objectors are entitled to be listened to. Though, doubtless, thoroughly able to judge on the value of work done by students of anatomy and physiology, it is at least questionable whether a pure physician would be altogether fitted to decide the necessity for duly testing that knowledge; nor can those who are not directly engaged either in teaching or in examining on the subjects in question, be justly held capable of forming conclusions on the point at issue. There can, of course, be no possibility of doubt that the commonly received ideas respecting the College of Surgeons is entirely erroneous. Even the figures recently exhibited so triumphantly by Mr.

Marshall now mean nothing, or he would not have been the one to insist on further sifting of candidates for the primary by imposing an additional compulsory examination. In spite of the very low percentage of rejections at the College, students present themselves so very ill-prepared, that nothing but a most rigorous filtering process can be trusted to strain off the few who really deserve to be admitted to the presence of the College examiners. This is, naturally, the only explanation to be found for Mr. Marshall's new examination, and that it is an admirable one few will be found to deny. It is right and just that the labour of the College should be reduced to a minimum, and likewise that it should relegate its hitherto labour to the schools which prepare the material it stamps for circulation. The College cannot be expected to waste time and effort in examination of ignorant students. Let the teachers whose fault it is that they know nothing, undergo the toil of proving their deficiencies, and of preventing them from making further exhibition of it to the disgust of examiners at the College.

Lecturers, teachers, and demonstrators should hail the opportunities presented by the new regulation. They cannot fail to see its advantages, which are, indeed, too obvious to escape detection at once.

THE ASSIGNED CAUSES OF ENDEMIC DISEASES IN INDIA.

THE offer of a prize of £100 by the Government of India for the best Manual of Hygiene for soldiers did not produce any work that was regarded as suitable, and the prize was, therefore, not awarded. The following abstract of a report by the committee appointed to adjudicate the prize has been published in the official *Gazette of India* for the information of the competitors:—"We have examined the 37 manuals submitted for competition, and are agreed that no one of them is, in all respects, suitable for the purpose for which a manual is required, as prescribed in the notification offering the prize. They all, more or less, contain theories regarding the causation of disease which are doubtful, and some of them are directly at variance with Indian experience. Their general tendency, moreover, is to exaggerate the dangers to health from local and climatic causes, and so to instil an unreasonable dread of Indian service."

That the decision thus expressed may have been right enough is very likely, and it would have been well had the committee appointed to examine the manuals submitted adhered to the golden rule—not to give reasons for their decision. As *theories* have been alluded to, the question presents itself, according to which of them is the prevalence of particular forms of endemic diseases at particular seasons and in particular localities and conditions best accounted for, and protective measures taken? Three *theories* are more or less popular, each supported by certain arguments. According to the first, our soldiers in India, like so many roaring lions, rush hither and thither, in season and out of season, seeking what they can get to devour in the shape of strong meats, stronger drinks, and tobacco, no less potent. Hence, according to the partisans of this

dozy, when "Thomas Atkins" sickens with fever or dysentery, the blame is conveniently assigned to himself. He may, indeed, have been, while on duty, exposed to sun, hot winds, heavy rains, sudden alternations of meteorological conditions. But all these go for nothing. Thomas Atkins drank too much, smoked too much, ate too much. He, naturally enough, therefore, got ill, and died, as very often happens. It was his own fault. But what had all that to do with climate? To this *theory* the reply is that in England the soldier eats, and drinks, and smokes just as much as he is able to do, and yet the diseases by which he sickens and dies are in their type and nature very different from those that affect him in India. Whence this difference? Evidently in climatic and other local conditions. Theory number two is of comparatively recent origin. According to it, flights and swarms of germs, spores, specific poisons, and what not spring into existence, from what ultimate cause is not stated; propagate themselves by means of milk-and-water, prostrate and destroy Thomas Atkins and his comrades in all directions, and then, by some means, as unexplained as that of their origin, themselves subside, disappear, and "go, we know not where." It is very true that no two persons agree as to the "specificity" of the "germs" alluded to; that "organisms" in all respects similar to those found in particular diseases exist also in persons who are absolutely free from any particular disease. It is equally true that neither in England nor in India is Thomas Atkins much "given to" indulgence in milk-and-watery potations. But these things are trifles. A "germ" theory has become fashionable in India as in England; all sorts of "sanitary improvements," many of them at very great expense, have, in accordance with this theory, been carried out, and the only result is that the particular diseases alluded to, instead of being abolished, as was fondly hoped, are prevalent as ever they were, and, in some instances, more fatal. Surely, therefore, there is something wrong about this *theory*?

The third and last dozy is that held by men "all of the olden time," namely, that, inasmuch as European animals and plants introduced into India deteriorate, become modified, sicken or die from the combined effects of the various influences, meteorological and other, to them new and unnatural, to which they are exposed, so does the human animal in the same alien climate suffer in ways more or less similar. To general influences of the nature alluded to were measures for preserving health of the soldier directed by the older medical officers, and with such excellent results that the standard of military health and efficiency in that country, long before the introduction into it of "specific" and "scientific" theories, compare very favourably with the results of more recent times in these respects. If the question of "theory," therefore, arises, and judgment is to be in accordance with results, let us re-introduce the last enumerated.

THE TUBERCLE BACILLUS.

THE interest in Koch's discoveries have been universal, and the subject has been discussed very fully in the medical journals of all languages, notably in the columns

of our excellent contemporary, the *Indian Medical Gazette*, the last number to hand of which contains a controversial article of considerable value. The tubercle bacillus takes its place among the *schizomycetes*, or cleft fungi of Nägeli, and presents similar morphological features to the organisms found in the charbon, septicæmia, and common putrefaction; but whether much, if any, significance is to be attached to some differences of shape and size in these organisms is very doubtful. The question of specific distinctions as depending on morphological features is an unsettled one, and, as far as we can discover, there is nothing in the description of this bacillus to warrant its identification as a new species. According to Koch, it can be discriminated from other organic matter and other bacilli by its reaction to certain colouring agents. The inoculability of the tubercle disease is a fact already well established by experiment. It may be held as demonstrated that associated with the tubercle disease and its products there is a bacillus. But is this bacillus the cause of tubercle? Is it the "germ" by which the disease is transferred from man to man, from animal to animal, from man to animal, and *vice versa*? That bacilli exist in tuberculous products no one will incline to deny. These materials are very prone to degenerate and decay, and in the decadence of living tissue and organic material, the development of micro-organisms is a familiar, if not universal, phenomenon. The question is: Are these micro-organisms the origin and cause of the tissue change which constitute the disease, or are they merely epiphenomena—organisms that are in a certain soil—the vital, physiological, or chemical changes really constituting the disease preceding their appearance. On the one hand putrid fluids containing micro-organisms have been injected into the healthy body and found to produce no marked disturbance. On the other hand, septic materials have been subjected to great heat, filtration, &c., calculated to exclude organisms or to deprive them of life, and these materials have been found to retain their virulence, and micro-organisms have been seen to develop in the products of the disease thus produced. It has been observed that micro-organisms arise very speedily in the blood and tissues of animals killed which have been quite healthy up to the time of death, and without any artificial introduction of germs or foreign material of any description. While, therefore, the association of micro-organisms with septic and other diseased processes is indisputable, there is very reasonable doubt whether these initiate the disturbance. There is, however, strong grounds for believing that if they do not initiate they aid in extending and perpetuating the disturbance; that they are not so much mischief-makers as mischief spreaders; that bacteria are not primary but secondary elements in a united process, and that their development is associated with a chemical, or at least unorganised process. Whether the poisonous properties—in the case of micro-organisms of Charbon—are acquired (in the process of development), are derived from imbibing the poisonous fluids in which they grow, or in a habit of metabolism due to the circumstances of their growth, is a matter of speculation. At any rate it seems premature to jump at the conclusion that Koch's bacilli are the specific germs of tubercle.

Notes on Current Topics.

Recognition of Foreign Diplomas.

APPROPOS of the proposition that foreign and Colonial diplomas shall be registrable in the United Kingdom if the Medical Council considers them worthy—which proposal is approved by the Royal Commission on the Medical Acts—it is worth while to notice that the Medical Council has, heretofore, recognised any or every preliminary examination offered to it without anything like due inquiry or consideration. They are now obliged to "try back" on their hasty recognitions, and have appointed a committee of expurgation for the purpose of weeding out examinations which have not the requisite value.

For the benefit of that committee we publish two illustrations of the American diploma trade, and we insist that a country where such traffic can be openly carried on has no right to expect recognition for its diplomas.

The *New York Medical Gazette* publishes the following:—

COLLEGE OF PHYSICIANS AND SURGEONS,
JOPLIN, MO., 5, 28, 1882.

GENTS.—Please send *price list of Doctors, and Druggist Names*, by states as I want to mail several thousand Annual Catalogues to the *Profession* all over the U. S. A. and Canada. I am starting an embryonic Pioneer Medical College and I must, of necessity, nois it around to the world to make it pay me. An early reply will greatly oblige your Respectfully, &c.,

J. C. PETIT, M.D., Dean.

The *Chemist and Druggist* also publishes a communication emanating from the Wisconsin Dental College which has been lately circulated among certain dentists in England, inviting them to remit 12 dollars for membership, honorary degree (D.D.S.), and diploma. The circular which we copy below was received by one of the chemists' assistants registered under the Dentists' Act who have been the objects of so much legal attention by the dental associations of this country. It bears a lithographed sketch of the "College," and runs thus:—

Wisconsin Dental College.—Incorporated under the Laws of Wisconsin.—Porcelain Plates a Specialty.—The third regular annual fall and winter session will commence October 16, 1882, and continue until March 1 ensuing. Several prominent practitioners have been secured to deliver special lectures during the term.

SIR,—Knowing you to be a regular practising dentist, we send the Wisconsin Dental College announcement, hoping you will endorse our position, making merit the qualification for graduation *regardless of time spent at the college*. As is the custom of other colleges desiring representation to *confer honorary degrees on worthy practitioners*, enclosed find printed form which you can fill out and return. Should your statement meet the approval of the faculty, we will make you a member of this college, and confer on you the honorary degree D.D.S. (Doctor of Dental Surgery), and forward you an elegant diploma, with your name artistically hand-printed (old English letter). This diploma is 17 by 22 inches, elaborately engraved, and printed on parchment deed, with signature of the faculty and college seal.

THE Sultan of Turkey has given a site in Jerusalem for the purpose of erecting a hospice and ophthalmic dispensary under the auspices of the English branch of the Order of St. John.

The Poor-law Superannuation (Ireland) Bill.

WE are pleased to be able to state that the Irish Poor-law Superannuation Bill, which was introduced at the beginning of the Session by Mr. Herbert Gladstone, at the instance of the Irish Medical Association and Union Officers' Association, and which has "hung fire" ever since, is to be proceeded with this Session, if the state of Parliamentary business admits. As Mr. Gladstone has ceased to be connected with the Irish Government he would naturally cease to have charge of the Bill, but we believe it has been arranged that he shall continue to act for the Chief Secretary with respect to the measure. The Bill now stands for a second reading, but it has forfeited the approval of the promoting Associations, because of the concession made at the first reading by Mr. Herbert Gladstone, who promised to conciliate the opposing irreconcilables by leaving the grant of a pension discretionary with the Board of Guardians. For this cause the Irish Medical Association is taking no steps to urge the second reading, but it will make every effort when the Bill goes into Committee to prevent this destructive alteration of the Bill being carried into effect.

Lady Doctors.

THE *Boston Med. Jour.*, alluding to the vote of the Medical Society at Harvard University against the admission of women to the medical school, says:—"We have neither space nor inclination to enter upon the already too vexed question of the general capabilities of women. Enough has been said about it. We think, as we have always thought, that time may be easily trusted to dispose of the 'woman-movement' to the best advantage of both sexes. But, regarding the extravagance of this movement, as we do, as a temporary enthusiasm, we welcome any indications that old and cherished institutions like the Harvard University are not to fall victims in their well-established usefulness to a social fermentation which history will, sooner or later, refer to simply as a singular phase of the sociology of the latter part of the nineteenth century."

The Influence of Light on Bacteria.

It has long been a matter of discussion how far bacteria are influenced by light, and the opinion more generally entertained is that their development is retarded or altogether hindered in the bright sun. In a letter to *Nature*, however, Mr. James Jamieson, of Melbourne, gives expression to views which, should they be confirmed, will tend to modify those that have been accepted in this connection. Mr. Jamieson has conducted a number of experiments with the object of verifying or contradicting the results obtained by other observers. His method consisted in inoculating Cohn's solution as a cultivation fluid with a small quantity of liquid swarming with bacteria, and placing this in bottles plugged with cotton-wool in the full rays of the sun. Some of the experiments were made in the hottest weather of February and March, and later in April. To begin with, the bottles were simply placed on the outside of a window-sill, on which the sun shone during the greater part of the day, a temperature of 124° F. being noted on one occasion, which was probably not the highest reached. Complete steri-

lization of the bacteria appeared sometimes to be obtained, but suspecting that the effect might possibly be due as much to elevated temperature as to chemical or other action of the sun's rays, Mr. Jamieson varied his experiments, being led thereto also by the observation that diffused light did not in any way check the bacterial growth when the solution exposed to it was kept approximately at the same temperature as similar bottles which had been surrounded with brown paper. It happened, moreover, that the exposed solution became opalescent sooner than that which had been guarded, and subsequent experiments tended to confirm the conclusion thus arrived at, that, viz., bacterial development is mainly, if not entirely, dependent on temperature. The most conclusive experiment is thus narrated by Mr. Jamieson:—"On April 6, at 2 p.m., the weather being bright, but cool, three bottles, containing each two drachms of inoculated solution, were suspended outside of a window. The 7th was cloudy; the 8th bright and cool; and on the 9th, which was bright and warm, all were found still transparent, and at 9 a.m. one was brought in out of the sun. On the 10th, which was also bright, another was taken in at 9 a.m., the one which was left out showing, at that time, faint signs of cloudiness. A thermometer hung up beside it marked a temperature of 98° F. Next day, the 11th, at 9 a.m., the exposed solution was quite milky, the others just beginning to show traces of opalescence, the one removed on the 9th being least advanced. In another experiment two bottles continuously exposed to the sun for two bright days became milky, although no trace of cloudiness had shown itself during five previous days, which were dark and cold."

The First Commencements of the Royal University of Ireland.

LAST week the first meeting of the Senate for the conferring of degrees and diplomas was held. The candidates numbered about forty, and they came up from the three Queen's Colleges—Belfast, Cork, and Galway—to obtain medical degrees only. This they were enabled to do (having passed the requisite examination) under the arrangement made to secure the academic status of students of the Queen's College in the new University.

Lord O'Hagan, who occupied the chair, was attired in the black and gold robe of the Vice-Chancellor, and he briefly expressed the gratification he had felt at meeting for the first time a body of the graduates of the Royal University of Ireland. The list contained the names of 29 M.D.'s, 29 M.Ch.'s, 14 obstetric diplomates, 52 second exam. students, and 73 first exam. men.

THE highest death-rates per 1,000 in the large towns last week from diseases of the zymotic class were—From whooping-cough 1.5 in Bristol and 1.2 in Birkenhead; from measles, 2.5 in Huddersfield and 1.8 in Birkenhead; from scarlet fever, 2.4 in Nottingham and 1.4 in Wolverhampton; and from fever, 2.0 in Portsmouth. Of the 28 deaths from diphtheria 16 occurred in London, 4 in Edinburgh, and 4 in Glasgow. Small-pox caused 8 deaths in London and its outer ring of suburban districts, 4 in Birmingham, 3 in Nottingham, and one in Manchester.

Guy's Hospital in Trouble again!

THE pertinacity with which trouble pursues the unfortunate institution in the Borough is something marvellous. Once more it has figured in an unenviable manner as the object of censure by a jury, the cause this time being the issue of death certificates in connection with the deaths of children soon after delivery by students of the hospital. The question raised by this publication of a system that is of necessity followed throughout the kingdom, is a most important one. An inquest was demanded by the Registrar of the district in which deaths of certain children occurred, and which deaths were certified on the representations of students who had acted as physician-accoucheurs at their birth. The Registrar refused to accept such certificates, as, indeed, he was quite right, from a legal point of view, in doing. If, however, this is always to be the rule in such cases, education in midwifery will no longer be possible, as also will be compliance with the regulations of examining boards in this particular. Moreover, the valuable aid lent by hospital students as accoucheurs will be cut off from the densely populated neighbourhoods of great towns, and an incalculable injury will thus be done to both the profession of medicine and the labouring poor. Notwithstanding this, it is difficult to see at the moment how the dilemma is to be compassed, and though Guy's Hospital is by an accident made to be the present scapegoat for an offence common to all hospital charities to which medical schools are attached, it must be admitted at once that it sins in common with the rest. We must for the time wait to see what results will follow the representations made by Mr. Payne, the coroner, to the Registrar-General respecting the practice complained of.

The Sanitary Institute.

ON Thursday last, at the Royal Institution, London, Mr. E. E. Robins, F.S.A., delivered an address on the work accomplished by the Sanitary Institute of Great Britain, now in its sixth year of existence. The chair was taken on this occasion by the Duke of Northumberland, who announced that Newcastle-on-Tyne had been selected as the place at which the next Congress of Sanitarians in connection with the Institute would be held. He adverted to the benefits which had followed from the action of the Institute in the past, and particularly referred to the advantages traceable to the annual congresses. These meetings are undoubtedly of great use in disseminating ideas and knowledge of the principles of sanitary science. The exhibitions which have been held have likewise done much to advance the study and practical application of hygienic laws, and there is every reason why the Institute should take credit to itself for its action in forwarding the holding of local exhibitions of this nature. The Sanitary Institute is doing good work, and should be encouraged to persist on the lines it has followed with such success.

H. W. P. WILSON ("Flora") finds that in many plants the excretion of carbonic acid decreases at once if a supply of oxygen is excluded. Hence the view that the carbonic acid exhaled by plants has its origin in inter-molecular decompositions, independent of the oxygen of the air, is untenable.

Illegal Death Certificates.

MR. SAMUELSON, M.P., has given notice of the following question:—To ask the Secretary of State for the Home Department whether his attention has been called to reports in the daily papers of July 6th of an inquest held before Mr. W. J. Payne, on July 5th, in the High Street, Boro', upon the bodies of some children, at which a physician of Guy's Hospital deposed that "it was the common practice to sign 'certificates of death' on the reports of the students, and without seeing the child at all;" and witness further said, in reply to the coroner and jury, that "they were quite aware that by the Act of Parliament they rendered themselves liable to a fine and two years' imprisonment by taking this course. He could see also that for the staff to sign certificates on mere information might sometimes lead to serious results;" and whether, in case of the recurrence of such illegal practices, he will direct the institution of a prosecution of the offenders by the Public Prosecutor.

The Medical Department in War Time.

THE committee which had been assembled at the War Office to investigate the charges brought against the Army Medical Department in South Africa has not yet made the required report. Major-General Sir E. Wood, V.C., K.C.B., chairman of the committee, having proceeded to the Mediterranean, it is to be hoped that his place on the committee may be speedily filled, if it has not already been so.

When we read of "charges" being brought against the working of the Medical Department on the very first occasion on which it has been put to the test, after what, according to some descriptions, is called its scheme of re-organisation—by others, that of *dis-organisation*—it is especially desirable that we should learn at least which of these expressions is the more applicable to it.

The Toleration of the Unqualified Assistant System by the Medical Council.

THE Medical Council, as our readers will recollect, has come to the extraordinary verdict, in connection with the practitioner who employed a notorious quack nigger "Colonel" to visit and certify his patients, that the practitioner was guilty of "infamous conduct," but ought, nevertheless, to be allowed to continue a registered surgeon. This outrageous palliation of the unqualified assistant system was pronounced by the Council on two pleas put forward by the accused:—*a.* That he *was informed* that the nigger "Colonel" had practised medicine in Canada, and had a Canadian diploma; *b.* That he never *authorised* the said "Colonel" to sign certificates in his name. The Medical Council acquitted the practitioner on these excuses, though he admitted that he had never asked to see the Canadian diploma, or made any inquiry into the truth of the "Colonel's" statements before he entrusted that person with the lives of his patients. Furthermore, no member of the Council seems to have thought of asking the question whether the practitioner, though he did not formally authorise the forging of his name to certificates, did not knowingly permit it to be done. In no part of the practitioner's explanatory statement do we find any such assurance. This case proves

abundantly that no confidence can be reposed in the Medical Council as regards the honour of professional practice, and it explains the reason why certain members of the Council have promoted a clause in the Medical Acts Amendment Bill to enable them to gloss over such acts as those of Dr. Murdoch. If further evidence of the readiness of the Council to stand by convicts and other disreputable practitioners were wanted, we could find it in its published proceedings last week, where we read that they were only prevented by a legal difficulty from restoring to the Register the erased name of a convict; that they erased only by a narrow majority the name of a person convicted of arson; and that they refused to weed out a practitioner who had been convicted of adultery with his patient's wife.

Conviction of Two Quacks.

In our issue for May 17th (page 425) we gave an account of the doings of certain impostors, who were making an unauthorised use of the names of the *Lancet* and the *Medical Press* to further their abominable designs. Our attention being called thereto, we instituted inquiries, and found that certain persons, one of whom had been before convicted, were advertising through various channels a preparation which was to do more for suffering humanity than "the discovery of vaccination and the circulation of the blood." The name of Sir John Fleming, M.D., was coined, and commendations purporting to come from the two medical journals referred to were adduced to give a colouring of respectability to the enterprise. Satisfied that a base fraud was being perpetrated on the public, as they were selling the wretched stuff at ten guineas per case, we at once called the attention of the police to their abode and doings, which last week culminated in the conviction of the two principals concerned, named Sutton and Brownrigg, to five years' penal servitude. We are happy to congratulate the authorities on their promptitude. Not a moment was lost in prosecuting our inquiries further and arresting the culprits. Such action should have a wholesome influence on the quack fraternity at large, some of whom are, thanks to our efforts in the past, still "languishing in blighted obscurity."

Calf Vaccination.

On Monday week Mr. Dillwyn, on behalf of Mr. Hopwood, asked the President of the Local Government Board whether the Board was prepared to advise the public which of the two modes of vaccination now in use was to be preferred—viz., the matter derived from arm-to-arm, or the one with the lymph from the calf recently provided by the Department; and whether it had been shown that tubercle may be transmitted by such lymph. Mr. Dodson said the Local Government Board, after long experience of vaccination from arm-to-arm, had every confidence in its efficiency. They had not had experience on any large scale of vaccination with lymph direct from the calf, but they believed it to be equally trustworthy. In regard to the second part of the question, the Board were not prepared to offer any advice as to the preference to be given to one form of vaccination over the other.

Redundant Titles.

A CORRESPONDENT has challenged our opinion respecting the propriety of an hospital surgeon assuming a number of titles unknown to hospital surgeons in general, which—though mere synonyms for the ordinary and proper designation of the surgeoncy—are made to do duty as separate surgical distinctions. The question is submitted to us with special reference to a recent publication of cases by a Dublin surgeon, who describes himself not only as senior surgeon to the hospital, but also as "Teacher of Operative Surgery and Visiting Clinical Surgeon" to his hospital. In our opinion this system is to be deprecated as misleading, and tending to an indefinite appropriation of unreal titles. Every hospital surgeon in any centre of medical education is a "teacher of operative surgery and visiting clinical surgeon" in the same sense as is the gentleman who so styles himself, and it is—in our opinion—not right for anyone to assume deceptive titles which may lead persons to believe that the "teacher of operative surgery" is a specially-appointed professor of surgery, or that the "visiting clinical surgeon" has any clinical visits to pay other than his daily round of the hospital wards. The assumption of such titles does not seem likely to add credit to the person who uses them, nor is it fair to other hospital surgeons.

The Antiphlogistic Action of Blood-letting.

WITH a view of proving by actual demonstration, the action of local blood-letting Dr. Gänziner made a number of experiments on Herr Nikolas, a medical candidate, the result of which he has published in the *Med. Wiss.* It appears to him to be proved by these experiments that the antiphlogistic action of local blood-letting is a purely mechanical one. The blood corpuscles, which are adhering to the walls of the blood vessels in the neighbourhood of an inflammation, are carried away by the increased rush of blood towards the part, when a leech sucks, or when blood is withdrawn by a cupping glass or scarification, the blocked up capillaries are flushed, and a normal—even an accelerated circulation temporarily—is restored. Blood stasis is the first step towards the local death of tissues, and local blood-letting is antagonistic to blood stasis. Blood-letting not only does not cause local anæmia, but it even sets up (temporarily, indeed), an arterial hyperæmia, i.e., it increases the flow of arterial blood towards the inflamed mass. That the increased supply of arterial blood may result in a more perfect nourishment of the tissues, and that the better nourishment may put the structure in a position to successfully combat the exciting causes of the inflammation may be taken for granted. It was shown further that the antiphlogistic action of bleeding depended on the quantity of the blood withdrawn, and that in the first rank in importance stood rapidity of outflow. Wherever possible the blood should be drawn within the inflamed circle—between it and the right heart—and not far from it, if it is to act antiphlogistically.

ACCORDING to M. Danillo, the progress of poisoning by absinthe presents an analogy with the effects of strychnine.

Ambulance Arrangements in War.

THE conditions of modern war require that during battle the following ambulance arrangements be made—viz. :—

1. The field station for first help.
2. The transfer station, where the wounded are transferred from hand conveyances to wheeled conveyances.
3. The dressing station, where provisional dressings are applied.
4. The field hospital station, where definite treatment is applied.

These several arrangements are, however, open to modifications, as circumstances may demand.

The ambulance staff consists of—1. Bearers of wounded; 2. Surgeons and attendants; 3. Ambulance train personnel; 4. Ambulance police; 5. Servants to officers.

1. *Bearers*.—In the Germany army there are two classes of these—viz., the Sanitäts detachment, specially organised for the purpose; secondly, the Hilfs sanenträger, consisting of four men per company. In the British army, the men of the Army Hospital Corps and bandmen fulfil this duty. In India, dooly bearers are employed for the purpose.

2. *Surgical Staff* embraces the medical officers, dispensers, men and officers of the Army Hospital Corps, including orderlies, cooks, &c.

3. *Ambulance Train* includes all who are employed in conducting the wheeled transport, litters, caolets, &c. These are supplied by the Control Department.

4. *Military Servants*.—These are provided from regiments or from the Army Hospital Corps. In either case the arrangement is inconvenient.

5. *Ambulance Police*, arranged for by the Provost Marshal.

Equipment includes (1) medical and surgical, and (2) that for transport of the wounded :—

1. *Medical and Surgical*.—This has to be so distributed as to be readily removable, and easily packed and unpacked. This equipment is distributed as follows—viz., (1) dressings, medicines, and restoratives in small “medical field panniers” and in larger “field panniers;” (2) cooking vessels and other articles of field hospital service in “canteens;” (3) articles of light nourishment, stimulants, &c., in “medical comfort boxes;” (4) hospital tents, bedding, and the bulkier articles of surgical equipment in carts or store waggons. In addition, every soldier should carry on his person the means of first dressing.

2. *The Ambulance Equipment* includes (1) stretchers; (2) conveyances wheeled by men; (3) Mule litters and caolets; (4) wheeled conveyances drawn by horses—these are the ambulance waggons.

A new scale of medicines and medical stores has been issued by the Board of Trade Marine Department, and should be obtained by chemists who fit up medicine chests for merchants and passenger vessels.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows :—Madras 28; Paris

24; Geneva 16; Brussels 19; Amsterdam 22; Rotterdam 19, The Hague 18; Copenhagen 27; Stockholm 24; Christiania 15; St. Petersburg 44; Berlin 33; Hamburg 25; Dresden 25, Breslau 32, Munich 23, Vienna 32, Prague 28, Buda-Pesth, 38, Trieste 20, Rome 27, Turin 22, Venice 23, New York 26, Brooklyn 18, Philadelphia 19, and Baltimore 25.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were :—Norwich 13; Derby 14; Bristol, Plymouth, Brighton 15; Hull, Oldham 16; London, Birmingham 17; Portsmouth, Leeds, Bradford, Sheffield 18; Wolverhampton, Bolton, Salford, Sunderland, Cardiff, Preston 19; Edinburgh, Dublin, Blackburn, Leicester, Halifax 20; Birkenhead, Liverpool, Newcastle-on-Tyne 21; Huddersfield, Glasgow 22; Manchester 23; and Nottingham 24.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE CHAIR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.—We have to congratulate Dr. Chiene on being appointed to the Chair of Surgery rendered vacant by the death of Professor Spence. We have all along advocated Mr. Chiene's candidature, and we are, therefore, gratified at the result of the election on Monday last. At the same time it is but just to the other candidates to admit that they were equally worthy to fill the vacant post, should the choice of the Senatus have fallen on either of them.

EDINBURGH UNIVERSITY COURT.—At the last meeting of the University Court, Principal Sir Alexander Grant, Bart., in the chair, the following business was disposed of.

The Teaching of Practical Pharmacy.—Deputations on behalf of several of the city dispensaries and of the Scottish Branch of the Chemists and Druggists' Association were received in support of memorials given in by them on the subject of proposed alterations of the regulations for graduation in medicine in the University, objecting to these proposed alterations in so far as regards the class of practical materia medica. Professors T. K. Frazer and Greenfield attended on behalf of the Senatus. After hearing the deputations and the representatives of the Senatus, it was agreed, with a view to giving the members of the deputations time to consider a printed statement of the views of the Senatus on the matter, recently received, that decision should be postponed till the stated meeting in October; and that the bodies represented should give in a printed statement of their views before the end of September.

Examiner in Chemistry.—Mr. W. Dittmar was reappointed Examiner in Chemistry from 1st October next to the end of the current year.

Regulations relating to the Teaching of Pathology.—A proposed alteration of the regulations for graduation in medicine in the University of Aberdeen, in so far as they relate to the subject of pathology, received from the Privy Council Office for observations, was considered, together with a minute of Senatus expressing cordial approval of the proposed alteration, on consideration of which it was resolved to state to the Lord President of the Council that the Court saw no objections thereto.

Regulations as to Extra-Mural Teachers.—A [minute of

Senatus was considered, which contained a proposal to obtain an alteration of Ordinance No. 5, Edinburgh No. 2, with the object of permitting candidates for graduation in medicine to proceed to examination, in the first division of the professional examinations, at the first period of examination in that division after completing attendance on the subjects thereof, viz.—botany, natural history, and chemistry. The Court approved of the proposal, and gave instructions for the necessary steps being taken with a view to obtaining the approval of Her Majesty in Council thereto.

New Proposals as to Regulations of Examinations.—On consideration of a minute of Senatus, it was agreed to add to the rules regarding applications for recognition by teachers of medicine under Ordinance No. 8, section vi. (4), a requirement that applicants should furnish a general statement of the apparatus, illustrative specimens, and diagrams, or other appliances at their disposal for the instruction of their classes. The rules were revised in conformity with this decision, and otherwise amended.

DEATH FROM EATING SHELL-FISH.—Early on the morning of the 10th inst. two boys died at Rothesay, almost within the same hour, from eating shell-fish. The cases were not at first considered serious, and medical aid was not summoned until severe spasms had set in twenty-four hours afterwards, and it was then too late. Previously the boys had been in excellent health.

FATAL BATHING ACCIDENT TO A MEDICAL MAN.—About noon on the 10th inst. Dr. Morehead Macfarlane, Ardenadam, a retired Stirlingshire medical practitioner, while bathing in the Holy Loch seems to have been seized with cramp, and although taken ashore speedily thereafter, death was found to have occurred. Deceased leaves a widow.

ASSAULT AND ROBBERY ON A MEDICAL MAN.—A very daring assault was committed on Dr. William Whitelaw, of Kirkintilloch, on the 10th inst.—It appears that shortly after 11 o'clock p.m. a respectable-looking woman called at Dr. Whitelaw's residence and represented that his services were requested at Beechmount, a villa about a mile from his residence. After interrogating the woman the doctor accompanied her. After a brief interval the doctor heard voices behind him, and when he entered upon a secluded portion of the road, he was suddenly set upon by two men, who knocked him down, one of them inflicting a severe kick on his left ankle, thus splintering the bone and dislocating the joint. The ruffians at once proceeded to rifle him, the woman, who was an accomplice, assisting to hold him down. The only property he had was a clinical thermometer and pocket knife, as before leaving his own house he divested himself of his watch and valuables. It is not often that medical men are thus assaulted, as, even by criminals, a certain respect is retained for them. Much sympathy is felt for Dr. Whitelaw, who is deservedly popular in the district.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—The directors of this Hospital at their last meeting unanimously elected Professor Annandale to be consulting surgeon, *vice* Professor Spence, deceased; and Dr. Woodhead, of the Edinburgh University, as pathologist, *vice* Dr. D. J. Hamilton, appointed a professor in Aberdeen University.

EDINBURGH OBSTETRICAL SOCIETY.—This Society will meet in their Hall, No. 5 St. Andrew Square, this evening (Wednesday) at 8 p.m., when papers on the following subjects will be read:—1. Case of Extra-Uterine Fœtation. By Dr. A. H. Barbour; 2. Case of Extra-Uterine Fœtation. By Dr. C. H. Thatcher; 3. Two Cases of Atresia Vaginae. By Dr. J. Halliday Croom.

A MEDICAL ASSISTANT CHARGED WITH CULPABLE HOMICIDE AT DUMFRIES.—On the 12th inst., in the Dumfries Sheriff Court—Sheriff Hope on the bench—Samuel Walter Wright, student of medicine, and lately assistant to Dr. Smith, Dumfries, was charged with culpable homicide, in so far as on Sunday, 9th April last, having been called to attend the now deceased Margaret Brown, or Mackie, who was suffering from cramps or pain in the stomach, he did administer to her, by hypodermic injection, from 12 to 15 minims of solution of morphia, whereby she was immediately reduced to a state of insensibility, and died about four hours afterwards. At the first hearing the accused pleaded not guilty, but subsequently intimated his intention to plead guilty. It was contended on his behalf that there had been no culpable intention, but that the fatal consequences resulted from an unfortunate mistake. Sheriff Hope imposed a fine of £20, the alternative being a month's imprisonment.

DEATH OF DR. ANDREW BUCHANAN.—At the ripe age of eighty-four, one of the most respected members of the profession in Glasgow has just passed away in the person of Dr. Andrew Buchanan. He was one of the founders of the *Glasgow Medical Journal* in 1828, and his mental faculties were keen and vigorous to the last. A few weeks since our columns bore evidence of this in his contest on the vaccination question with Mr. Peter Taylor; but we defer our remarks to a full obituary notice of this, in many respects, remarkable man in our next.

Literature.

CLINICAL LECTURES ON SENILE AND CHRONIC DISEASES. (a)

(Continued from page 430, last volume.)

THOUGH we have given much space to the first nine lectures in this volume, it is not our intention to go on doing so at the same length. The remaining lectures no doubt are very interesting, and contain valuable information. But they relate to diseases with which, in Ireland, at least, we are more familiar, and with which Irish writers have made us well acquainted. We may notice here that our author seems to be very well read on all the writers, both English and Irish, who have published works on these subjects. Few of us, we guess, are indeed so well acquainted with them as the author. We notice the names of Hayarth, Heberden, W. Hunter, Colles, Adams, Smith, Garrod, Fuller, Redfern, Sydenham, and Musgrave. Of all these the author specially notices Adams' classical work, as he calls it, and which he says leaves very little to be desired. He quotes of course his own countrymen, and also many German names. In truth, these lectures show an immense amount of research, and the author selects from each writer the points to which he considers he has a claim.

We notice that when our author speaks of the character of the liquid effused into the joints, in chronic joint disease, that it is very exceptional when pus is found, but that commonly it is sero-fibrinous exudation. We believe this is correct, and that when pus is found, such as Bouilland describes, the case must then be placed in a very different category, which for ourselves we would call "diffuse inflammation." We have seen this occur, but it must be allowed to be very exceptional.

It has been stated already that our author holds there is a positive difference between gout and rheumatism, and that in the joints this is shown by the presence of the sodium urate in gout, whilst in rheumatism this salt is not found. To several other distinctions between the two affections the author draws particular attention, and we would add that this chapter, the XIII., is well worthy of perusal, though we cannot enlarge upon it further here.

In the chapters devoted to the treatment of the affections

(a) "Clinical Lectures on Senile and Chronic Diseases." By J. M. Charcot. Translated by W. S. Tuke, M.B.C.S. London: The New Sydenham Society 1881.

of which we have been speaking the reader will find a good reward of all that is known on the subject.

The next three sections, which were originally an appendix, relate to thermometry in the aged; and in the author's hands the subject is treated with great experience. He maintains that the rectum is the proper place to ascertain the animal heat; for that in the axilla the real temperature cannot be truly ascertained in the old. He further shows that very much the same course which goes on in adult and middle life, as regards the animal heat in disease, also obtains in the aged. We wish, indeed, we could enter more fully into the details of this portion of the volume, for they are very interesting, and of a highly practical character. We would particularly notice the author's observations on those cases where the temperature is below the normal. This is a class of cases which we ourselves had long observed, and recognised their gravity, and about which the account given by our author is the most complete with which we are acquainted. But we are forced to draw our remarks to a conclusion.

The volume ends with three lectures relating to the morbid anatomy of cerebral hæmorrhage. These are equally good with what has preceded, and this is saying much for them. It is illustrated by engravings, very well-executed, of examples of nodular rheumatism, and diseases of the minute arteries, as they affect the nervous structures, and the brain in particular.

We commend the entire volume to the special notice of our readers.

Medical News.

ASSOCIATION FOR THE ADVANCEMENT OF MEDICINE BY RESEARCH.

A MEETING of the Council of this Association was held at the Royal College of Physicians on the 12th inst. In the absence of the President, the Vice-chairman, Sir James Paget, took the chair. There were also present Dr. Andrew Clark, Sir William Gull, Sir J. Risdon Bennett, Dr. Quain, Prof. Lister, Prof. B. Sanderson, Mr. Bowman, Mr. Spencer Wells, Sir H. Thompson, Prof. Michael Foster (Cambridge), Prof. Gamgee (Manchester), Sir Joseph Fayrer, Dr. Balthazar Foster (Birmingham), Mr. Barron (Bide), and others.

The treasurer reported that several further subscriptions had been received, including the following:—Dr. Andrew Clark, £100; Mr. Prescott Hewett, £52 10s.; Dr. Chalmers, £3 2s.; Dr. Bull (Worcester), £1 1s.; Mr. Dent, £5 5s.; Mr. Laidlaw Purves, £5 5s.; Dr. Wilson Fox, £10; Dr. C. J. B. Williams, £10 10s.; Mr. John Marshall, £10 10s.; Dr. Payne, £10 10s.; Dr. Gamgee, £2 2s.; Dr. Bowles (Folkestone), £5; Dr. B. Foster (Birmingham), £20; Dr. Lucas (Bombay Army), £1 1s.; Dr. Donkin, £1 1s.; and others.

The secretary reported that the co-operation of several leading members of the profession in the chief provincial towns had been obtained, and that branch committees were being formed in Dublin, Edinburgh, Glasgow, Aberdeen, Manchester, and Birmingham.

With a view to the promotion of direct research it was resolved, after a report on the subject of a sub-committee had been read, that Mr. Watson Cheyne be requested to undertake the investigation (of tubercle) recommended by the sub-committee, and the treasurer was requested to issue a circular asking for subscriptions for the furtherance of direct research.

It was reported that the communications which had taken place between a committee of the Association and the Home Secretary gave promise of material improvement in the working of the Vivisection Act of 1876, and a resolution requesting the committee to continue their efforts in this direction was proposed by Sir Joseph Fayrer and carried.

The Bill for the Total Abolition of Vivisection brought into Parliament by Mr. Reid was discussed, and it was stated that most influential opposition would have been offered in Parliament had the Bill reached a second reading.

A memorandum which had been prepared for distribution among Members of Parliament, stating the nature, objects, and advantages of investigation by direct research was considered, and after discussion it was resolved that this, and also several papers and pamphlets on the subject which had been selected, should be printed and distributed for the better information of the public.

THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

At a meeting of the Council of the Poor-law Medical Officers' Association, held at 3 Bolt Court, Fleet Street, July 6th, it was resolved that the annual meeting of the Association should be held at Worcester during the jubilee of the British Medical Association, at an hour and day hereafter to be locally determined, due notice of which will be given. The Council trust that all Poor-law medical officers resident in the adjacent counties will, if practicable, put in an appearance, as many important subjects bearing on the well-doing of the service will be brought forward, notably the amendment of the Superannuation Act. The Council hope that if any gentleman has any grievance to complain of that he will communicate the facts connected therewith to Dr. Rogers, 33 Soho Square, London.

NESTLE'S MILK FOOD FOR INFANTS.

DR. GEORGE B. FOWLER has been analysing all the known infants and invalids' foods in the market, and has published the results of his investigations in the last number of the American quarterly *Journal of Obstetrics*. With respect to Nestle's Food he exactly confirms our views. He says:—

"This is a fine brown powder, with an attractive odour, resembling that of fresh cake, and decidedly sweet taste. A solution of it in a test tube reacts strongly to Trommer's test, and is turned blue by iodine. The microscope reveals masses of baked starch corpuscles, milk globules, and granular matter. On the addition of a drop of iodine solution most of the starch bodies instantly turn blue, some red (dextrin), while the granular matter remains unaffected. This latter, however, is stained red by carmine, proving it to be albuminous. Consisting, then, of wheat flour which has been subjected to dry heat to the extent to partially convert it into dextrin of glucose and dried milk, this preparation certainly possesses a high degree of nutritive value, and is an ingenious and elegant article."

Bradford Medico-Chirurgical Society.—At the twentieth annual meeting of this society, which was held in the board room of the Bradford Infirmary, the report expressed satisfaction at the number of members and the work of the society for the closing session. A report of the Commission on Woolsorters' Diseases, appointed eighteen months previously by the society, was read and ordered to be printed for private circulation amongst the members, previously to its general discussion at a forthcoming meeting. Votes of thanks were accorded to the retiring officers, and the following gentlemen were elected to serve for the succeeding year:—For President, Mr. H. Butterfield; for treasurer, Mr. T. C. Denby; for secretary, Dr. D. Goyder; for committee, Dr. J. Craig, Messrs W. H. Ellis, J. Appleyard, M.B., W. G. Burnie; for pathologists, Messrs T. Wilmot and J. Appleyard, M.B.; for auditors, Mr. S. C. Hirst and Dr. J. Dunlop.

University of Dublin.—The following candidates passed the examinations at the recent term of this University in the order of merit as given. For the Degree of Bachelor of Medicine (M.B.):—

James Chute, Thomas Robert Bradshaw, Benjamin Morgan Dockrell, William F. Law, William H. Bennett, Walter H. Longhead, Michael McHugh, William F. Patten, John N. Seymour, John Armstrong, Charles St. S. Nason, William H. Allen, Joseph Bulfin, Vicars H. Fisher, George Lloyd-Apjohn, William A. Carte, Augustus M. Whitestone, Daniel Crowe, William H. Peard, Robert H. Fleming.

At the same examination, the following senior candidate also passed:—

A. Rice Oxley, B.A. Oxon., M.R.C.S. Eng., L.S.A.

For the Degree of Bachelor of Surgery (B.Ch.):—

William H. Burke, James Chute, Benjamin M. Dockrell, Travers R. M. Smith, Walter H. Longhead, William F. Patten, George Frederick Dean, John N. Seymour, William Francis Law, Chaworth L. Nolan, James S. Carson.

For the Degree of Master in Obstetrics (M.A.O.):—

Benjamin Morgan Dockrell.

Royal College of Surgeons, Ireland.—The following prizes were recently awarded in connection with the Medical School:—First Year's Class: First prize (£10), Geo. E. Greene; Second prize (£5), Richard H. Fetherston. Second Year: First prize (£12), Wm. L. Symes. Senior Class: First prize (gold medal and £10), Austin N. Cooper; Second prize (£10), Myer J. Dutch.

Royal College of Physicians, Edinburgh.—The following candidates have passed the examination for the diploma of L.R.C.P. of this College:—

George Alfred Roe, Stoke; Andrew Fuller, Wolverhampton; William

Thomas, Anglessea; Charles Donkin, London; Thomas Englab, Adamstown; Herbert Chaworth Hallows, Clapwell Hall, Chesterfield; Thomas Thomson, London; Henry E. Haycock, Shrewsbury; William Henry Evans, Seaton; Robert N. Clements, Glasgow; George H. Phillips, Bridgnorth; and James W. Ribey, Birmingham.

Notices to Correspondents.

DR. T. P. will be gratified to learn the excellent result of inquiries and vigorous action in the case about which he inquires on reference to our "Notes on Current Topics."

ONE INTERESTED.—The amount collected is slightly in excess of previous years, but it is not half what it should be. The Council of the Fund meets to-day to apportion amounts, of which we hope to give a full statement in our next.

DISPUTANT (Glasgow).—Dr. Andrew Buchanan, of your city, has hitherto been accredited with the initiative. We believe he founded the journal in question in 1828, but he was not its first editor, vol. I. being edited by Dr. William Mackenzie, celebrated in his day as an avrist of considerable eminence. Vol. IV. bears the imprint of Dr. Buchanan as joint editor with the late Dr. Wm. Weir. We shall return to the subject fully in our next.

CORONERS (IRELAND).—"Coroner" asks: 1. Who appoints to the office of coroner? 2. Does the L. G. Board permit dispensary doctors to hold that appointment? 3. Are there any special qualifications required for the office?

[1. The Parliamentary electors of the district. 2. The L. G. B. objects strongly, but cannot prevent a dispensary surgeon being appointed coroner, though it refuses to sanction the appointment of a coroner to a dispensary district. 3. Under sec. 2 of Coroners' (Ireland) Act of 1881 ("Irish Medical Directory," page 625), coroner must be—(a) A registered medical practitioner; (b) A barrister; (c) A solicitor; or (d) A magistrate of five years' standing.—Ed.]

MR. FRANKLIN is thanked, but the communication is more suited to the columns of our contemporary the *Students' Journal*.

HOWARD.—We understand that four essays have been sent in competition for the 1883 medal and prize.

THE CONTAGIOUS DISEASES ACTS AND THE SELECT COMMITTEE.—The Select Committee on the Contagious Diseases Acts will meet in a few days to consider their Report. Two draft reports have been prepared, one recommending the entire repeal of the Acts, by Mr. Stansfeld, and the other substantially in favour of maintaining them, by Mr. O'Shaughnessy.

DR. ABRATH VERSUS THE NORTH-EASTERN RAILWAY COMPANY.—An action was commenced on Monday at the Durham Assizes by Dr. Abrath, of Sunderland, for compensation for malicious prosecution by the North-Eastern Railway Company. The original action, it will be remembered, was instituted some few months since by the Company against Dr. Abrath and a patient named McMann for attempted fraud; the verdict was against the Company, and the present is an action for damages for malicious prosecution. The case is likely to last several days.

PLACENTAL LIFE.—"Veritas" asks: How long could a child live with the placenta attached?

[If a child be born and the placenta expelled immediately after, and the funis be not tied, the circulation in the funis would cease in a few minutes after respiration was thoroughly established, and the child would probably live equally well as if the funis had been tied in the usual way. The question is so vaguely put that it is not easy to understand what "Veritas" exactly wishes to be informed of.—Ed.]

MR. GIMSON.—There is no reason to anticipate anything unusual in the course of the case. An ordinary antipyretic treatment is all that it requires, with due attention to the diet, both during the acute stages and subsequently in convalescence. Messrs. Burroughs, Wellcome, and Co., or any chemist in your own town can afford you the requisite aid.

DR. S. S.—We cannot undertake to advise you in any other way. It appears to us that you have been wisely counselled, and that your best plan will be to follow the suggestions made by your solicitor.

POTT'S FRACTURE—APHASIA.—"Nemo" asks: 1. How long is it necessary to keep applied Dupuytren's splint in case of Pott's fracture occurring in a healthy man of 32 years? 2. When may he attempt to stand on the leg? 3. What measures may be taken to strengthen the internal lateral ligament? Would Martin's bandage be of use? 4. What incipient disease does omission and displacement of letters while writing quickly denote in a person of middle age, formerly a most correct penman?

[1. Pott's fracture generally requires the application of a retentive apparatus for about six weeks, after which time the patient may stand on the leg for daily increasing periods. It is, however, better not to keep the limb in splints for the whole time. The best plan is to apply the splint for from a week to a fortnight, and then put the leg up in a plaster-of-Paris bandage. 2. The patient can be allowed to walk with a crutch, keeping the foot off the ground, as soon as the plaster has dried. If splints are employed during the entire period of treatment it involves the confinement of the patient to bed or to a sofa. 3. The application of a stream of cold water, followed by plentiful friction two or three times daily, is the best way to restore and strengthen the parts. 4. It is difficult to offer an opinion on such slight evidence; but the omission and displacement you speak of are probably indicative of aphasia. A careful consideration of the entire

symptomatology of the case would be necessary in order to pronounce this opinion definitely, or to trace the probable origin of the aphasia.—Ed.]

MR. H. K. S.—If you will give us a call when in town we shall be happy to discuss the matter. The results, so far, are eminently encouraging.

DR. BAYNE (Brighton) will receive a private note.

DR. VALLARDI (Milan).—We regret that we cannot further increase our Exchange List.

DR. J. S. (Manchester) will find that his ideas have been anticipated if he turns to our last volume Index, letter "H." Verily "there is nothing new under the sun."

Vacancies.

Cumberland Infirmary, Carlisle.—Assistant House Surgeon. Salary, £60, with board, &c. Applications to be sent to the Committee not later than July 25th.

Durham County Hospital.—House Surgeon. Salary, £100, with free board and lodging. Further particulars may be obtained of the Hon. Sec., by whom applications will be received up to July 24th.

Flintshire Dispensary.—House Surgeon. Salary, £100, with furnished house, &c. Knowledge of the Welsh language is necessary. Applications to be sent to the Hon. Secretary on or before July 24th.

Hartlepool Hospital.—House Surgeon. Salary, £80, with board, &c. Applications to be sent to J. Rawlings, Esq., at the Hospital, Hartlepool, on or before July 24th.

Rathfriland Union, Aughrim Dispensary.—Medical Officer. Salary, £120, and the usual fees for vaccination. Election, July 29th.

Royal Isle of Wight Infirmary, Ryde.—House Surgeon and Secretary. Salary, £50, with board, &c. Applications to be sent to the Secretary before August 8th.

Appointments.

COSSHAM, W. R., M.D., C.M. Aber., M.R.C.S., Medical Officer to the Central District of the Cirencester Union.

DEELEY, A. W., L.K.Q.C.P.I., Medical Officer to the Sherburn District of the Scarborough Union.

FENWICK, B., M.D., M.R.O.P., Assistant Physician to the City of London Hospital for Diseases of the Chest.

GEM, W., L.K.Q.C.P.I., L.R.C.S.I., Assistant Medical Officer to the Workhouse Infirmary, City of London Union.

HOLLIS, E., M.D., C.M. Edin., House Surgeon to the East Suffolk Hospital.

MACMANUS, Dr. G., Admiralty Surgeon and Agent for the District of Trim, &c.

MORRIS, M. F.R.C.S. Ed., M.R.C.S., Surgeon to the Skin Department at St. Mary's Hospital.

RICH, Dr. C., Honorary Medical Officer to the Liverpool Dispensaries.

SECOMBE, G. S., L.R.C.P. Lond., M.B.C.S., Medical Superintendent of the Colonial Asylum, Port of Spain, Trinidad, West Indies.

SINCLAIR, J., M.B.C.S., Resident Medical Officer to the Queen Adelaide Dispensary, Bethnal Green.

THORNTON, B., M.R.C.S., L.R.C.P. Lond., House Surgeon to St. Mary's Hospital.

THOROWOOD, J. C., M.D., F.R.C.P. Lond., Consulting Physician to the Hospital for Diseases of the Chest, Victoria Park.

VAN BUREN, K. H., L.R.C.P. Ed., M.R.C.S., House Surgeon to the Buckinghamshire General Hospital.

Marriages.

BARR—WOOLLEY.—July 12, at Holy Trinity Church, Liverpool, James Barr, M.D., 1 St. Domingo Grove, Liverpool, to Belle, second daughter of the late J. Woolley, Esq., Springfield, Everton, Liverpool.

WALSHE—COPINGER.—July 6th, at Ghent, Belgium, Thomas Patrick Walshe, M.D., Ballinakill, to Kate, daughter of the late Christopher Copinger, Q.C., of Abbey View, Dalkey.

WRIGHT—BATEMAN.—July 12, at St. Raviour's, Aberdeen Park, N., by the Rev. Geo. Bellby, M.A., cousin of the bride, assisted by the Rev. J. Allen Fell, M.A., Vicar of Hayling Island, Hants, Christopher St John Wright, M.B. M.R.C.S., of Priors Marston, Warwickshire, to Agnes Louisa, daughter of the late Henry Bateman, F.R.C.S., of 13 Canonbury Lane, N.

Births.

DALY.—July 12, at 185 Amhurst Road, Hackney Downs, the wife of Frederick H. Daly, M.D., of a son.

Deaths.

BOLTON.—July 11, at Dulwich Road, London, William Bolton, M.D., late of Drumconrath, Priorland, Carrickmines, co. Dublin.

BUDGETT.—June 19th, at Gildridge Road, Eastbourne, John Burgess Season Budgett, M.D., L.R.C.P., aged 72.

COTTON.—July 12, at the Royal Naval Hospital, Stonehouse, Inspector-General John Cotton, M.D.

DODGSON.—July 10, at Derwent House, Cockermouth, Henry Dodgson, M.D. Edin., L.R.C.S., aged 49 years.

GILLESPIE.—July 6, at his residence, Aughrim, co. Wicklow, M. J. Gillespie, M.D., B.A., aged 37 years.

POTTER.—July 7th, at Chipping Ongar, Essex, Frank Dobson Potter, M.B.C.S., L.S.A. Lond., in his 72nd year.

TAYLOR.—July 9th, at West Brighton Crescent, Portobello, N.B., James Taylor, M.D., Deputy Inspector-General of Hospitals.

WIGHT.—June 25th, at St John's, Canada, East, Montreal, in his 50th year, Robert Wight, M.D., late of London.

The Medical Press and Circular.

A Course of Lectures

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE IV.

MR. PRESIDENT AND GENTLEMEN,—We turn to-day to a new department of our subject. I have been dealing hitherto with fixed inborn peculiarities which are for the most part beyond our explanation, but in consequence of which disease in individuals assumes very peculiar features. How peculiar and exceptional those features may be I have illustrated by the production of cases of bullous, pruriginous, and even gangrenous varicella, and of two examples of gangrenous vaccinia. I have also reminded you of the great differences in different individuals in the type and severity of syphilis, and I have shown, too, how, not only may the exanthemata sometimes attain most unusual severity, but how not unfrequently all their usual symptoms may seem to be suppressed and the patient may pass through a complete attack scarcely knowing that he has been ill. We have further glanced at the facts which prove that the iodides and bromides, remedies in daily and most frequent use, and for the most part very harmless, may occasionally act as violent poisons. Lastly, I have urged that in many other morbid processes originating in connection with ordinary and known causes, or it may be from local infection, the peculiar constitution of the individual takes an important share as well in increasing the proclivity as in modifying the result. Instances of this I found in such diseases as diphtheria, erysipelas, and carbuncle. Respecting these and other examples of personal proclivity or immunity which I have ventured to cite, I have maintained the same argument that they are all independent of everything that is to be recognised in the state of health of the patient, but they imply that which is conveniently

known as idiosyncrasy. Much, indeed, almost all, that I have advanced is, I am well aware, by no means novel. I have been dealing with old names and well-established doctrines, and my reason for bringing them before you has been not so much the hope of being able to contribute new facts or theories of my own as the desire to set in better order that floating knowledge which is a general possession. In the lecture which is yet to come I shall restrict myself to the same design, I hope. I am going to ask your attention to a great number of topics, to many of which I shall advert with such brevity that it would not be possible for me to enforce original views even if I possessed them. The bond of connection which will associate these various subjects will be the endeavour to discover whether there exists any larger groups or states of personal peculiarity giving special proclivity to diseases which can be suitably defined and named. If the reply to this question be in the affirmative—if we see reason for believing that those who become our patients do really differ one from another in respect to definite tendencies which are of prolonged duration and upon the knowledge of which we can conveniently not only have our prognosis but our treatment, it will next be our duty to examine as to the real nature of those states and the laws under which they came into being and continue to exist. I have dismissed the consideration of temperaments as being when correctly limited an unproductive field of research, but in doing this I expressed a belief that the investigation of the diatheses stood in a very different position. In the one we deal with the peculiarities of race and the results of what may be termed breeding, in the latter we begin much nearer home and investigate the consequences of a variety of influences which are capable either separately or together of producing chronic disease. For, in fact, what we mean by a diathesis is little less than an exceedingly chronic disease. It is a disease or taint which lasts a lifetime, which may be active at times, and latent at times, and which may be handed on to another generation. If we accept as a definition of diathesis that it is any condition of prolonged peculiarity of health giving proclivity to definite forms of disease, we must admit at once that it will comprise groups of maladies which are very different in their nature. Of some of these states the causes are very definite and specific, whilst of others they are much the reverse. Of those which are most definite, such as leprosy and syphilis, it may perhaps almost be doubted whether there is any convenience

in calling them diatheses at all. In certain stages when the disease is active there is assuredly no object in using any other word than the substantive name. It is chiefly when external symptoms are absent for a time in the individual, or when we witness the phenomena of hereditary transmission that we feel to need the addition of such a word as diathesis. It is in most conditions easy to say of an individual he has got syphilis, or he has not got syphilis, he is the subject of leprosy; for the disease in each instance is a definite one, and there is no such thing as a state of physical proclivity to either. Such maladies, however prolonged may be their possible duration, stand in the very different category to scrofula, rheumatism, or catarrh. These latter are diatheses which may vary within the widest limits in the individuals, and are so common as to be well-nigh universal. We can scarcely assert of any one that he is free from them, and the question is rather as to estimation of the degree. They are diatheses in the truest sense of the word, and they belong to the whole human family, and possibly, indeed, to all vertebrate animals. The more important questions to be put in reference to them are not, have you got rheumatism, scrofula, catarrh? but rather, in what degree are you catarrhal, rheumatic, scrofulous? The degree of susceptibility in each varies exceedingly in different persons, and in many instances rises to such a height that it constitutes a very serious disease. To these so to speak universal diatheses I shall have to recur in my last lecture.

In the same sense that we seek to know respecting our patients whether they possess more than usual proclivities to rheumatism and the like, we also inquire respecting various other states. Has he been injured by malaria? Has he been exposed to the causes which produce bronchocele? Has he a tendency to cancer? Is he gouty? Has he any permanent peculiarity of the circulation giving tendency to local disease, or of his blood-vessels causing risk of hæmorrhage? In these and various other directions we see our way to the construction of a host of diatheses of less importance than those we have mentioned only because they are less common. In the present lecture I shall glance at certain general groups of diatheses arranged according to their cause and in the two subsequent ones I shall take various special diseases or isolated symptoms and examine in respect to each how far it is possible to make use of it as a clue to the diathetic state producing it. Our knowledge of many of the diatheses is for the present far too vague to admit of our attempting any satisfactory classification of them, and a further difficulty occurs in the fact that their differences are often very dissimilar in kind. We might suggest a group of those which are transitory and those which are permanent, and others of those which may be acquired, and those which are solely obtained by transmission. It is clear, however, that any such grouping as this would often necessitate our placing the same malady in more than one class. On the whole, I think the simplest plan will be to make for the present a rough classification of the causes of diatheses, a task far easier than that of diatheses themselves, and following this, I shall bring before you a few examples of each.

I will commence first with diatheses in relation to climate. Under the term *malaria* we may include all the various emanations from marshy ground, swamps, and jungles. As to its exact nature we know nothing but that, whilst similar in essential qualities, it varies in different localities, both in intensity and character seems certain. Its effects upon the human constitution may be to produce quickly very severe disease, but, whether acute or otherwise, attacks of arterial spasm denoted by visceral congestions are almost constant phenomena. Its effects, whether exposure be continued or otherwise, are always permanent. The man who has once had ague will display through life peculiar susceptibilities. Under all circumstances likely to cause shivering he will show especial tendency to rigor. He will shiver if a catheter be passed, or if he be exposed to cold, or if inflammation is initiated, and it becomes a matter of some practical importance to the operating surgeon to remember that rigors occurring to such patients are not so serious in their import as in others. They are retrospective symptoms, and reveal the fact that those to whom they occur have at some former period come under the influence of malaria. One attack of malarial fever by no means prevents another, and although subsequent attacks are usually less severe than the first, yet the effects of the poison are distinctly cumulative, and the limits within which acclimatization can secure immunity

are probably much more narrowed than has been supposed. It is easy to see that a poison which can be so persistent in its action and of which the effects, even in mild cases, are so well nigh permanent, must be capable of producing that state of body which we name diathesis. The malarial diathesis is, indeed, a well-marked one, and it exists in greater or less degree in all who have ever come under the influence of its cause. It is probably in some degree hereditary the inheritance being, we may suppose, in ratio with the severity and length of duration of the disease in the parent. Inasmuch as the offspring of those who have suffered are usually born under conditions of continued exposure, it is difficult in them to discriminate between what is inherited and what is acquired. So great, however, is the combined influence of the two that a fearful state of physical degradation may be thus produced, and in this the inhabitants of a whole district may be involved. Nor is the physical health alone affected; the nervous system is especially involved, and the mental and moral faculties are largely influenced. When we remember how permanent in hereditary transmission such influences become, we can easily understand that the malarial diathesis has, in many instances, had a large share in controlling the destiny of a nation or damaging the character of a race. This diathesis can easily mix itself with any other, and in London practice we encounter it very frequently in association with that of syphilis, and occasionally both with it and that of alcoholism. I am speaking, of course, not of London residents, but of those who have lived abroad. Another climatic diathesis which must be placed side by side with that due to malaria is the one which results in bronchocele and cretinism. Here, again, we are ignorant of the precise cause, but we know that it appertains to certain local telluric conditions, and especially to mountains and valleys, just as we know of ague that it belongs to marshes. The cause of this diathesis is much more slow in its effects than is malaria. Far longer residence in the locality is required, and for its worst effects it appears to be essential that there shall have been transmission through several generations. It appears to persist with considerable tenacity in families which have once suffered from it. Like malaria, it degrades the entire man, and whenever prevalent produces certain deterioration of race. This diathesis, like several others, may perhaps be most conveniently named, from its most conspicuous symptom, the bronchocele diathesis. It is absurd in the case of that endemic disease to speak of bronchocele only, since the general health is always at the same time involved. At the risk of being accused of repetition, I must here again insist upon the features of distinction between diathesis due to food and those to be assigned to climate. The latter are distinctly restricted and endemic; the others not so. The latter, when severe, attack all immigrants who come within their range of influence, without regard to health, position, or habits, and under certain circumstances leave scarcely any exempt. The diet diathesis, on the contrary, as illustrated by leprosy and the like, affects immigrants only very seldom, and with great apparent capriciousness, taking one and leaving a thousand untouched.

A proof of diathesis of great importance is constituted by those persistent constitutional conditions—sometimes hereditary, at others not so—which have their origin in connection with food. Of these by far the most important for us, as English surgeons, is gout. Perhaps I ought to have assigned the foremost place to scrofula, and I should, indeed, have done so, but that it probably acknowledges a mixed causation. In many gouty patients the sum total of the diathesis is, as regards its causes, mixed. There may be susceptibility to weather, and to influence on the nervous system, as well as to articles of food, but these we can separate from what we mean by gout itself; and so far as this is concerned, I believe we will acknowledge that it is a question of diet. About the intermediate steps of causation there may be room for much discussion and difference of opinion. But I suspect that no one will decline to accept the suggestion that had mankind continued to be vegetable feeders, and never known the use of wine or beer, we should have had no experience of gout. If this be granted it is all I ask, for it is to be freely admitted—nay, expressly asserted—that such a thing as uncomplicated diet gout is now scarcely to be met with. If, however, we can succeed in any degree in separating its complications from itself, we shall find in gout the best type from which to study the laws of diet diathesis. In my own mind,

leprosy stands next to gout in the certainty that it is due to food, but I cannot speak as to this theory of its origin as being yet generally admitted. Certain general statements may be expected to be found true concerning all diatheses which are due to food. They ought to be the same, or nearly the same, in all countries and climates where the same diet is used, and they ought to cease where the diet is wholly changed, and to undergo modification, or to become rare, when it is modified. To some extent they ought to be curable by abstinence from the articles of food supposed to be their cause; but we must not push this too far, since many constitutional conditions, when once established, may persist, or even become hereditary, after the removal of their true cause. I scarcely need recapitulate the facts respecting gout which proves its association with dietetic habits. They are too well known. It may be well, however, that we should be reminded that the diathesis, when once established, becomes by inheritance remarkably persistent, and that it is unquestionably the parent, when so transmitted, of many very peculiar maladies of which the affiliation might easily have been overlooked. I went into some details in one of a former series of lectures to describe a peculiar form of destructive inflammation of the eyeball, a chronic and almost painless irido-dialysis which occurs only in those who inherit gout, and I shall not now say more respecting this disease than that I have, since my former lecture, seen some remarkable cases which supported the views then propounded, and none at all which were exceptional to them. There are several other less definite, and still less common forms of eye disease which stand, I believe, in the same relation to gout, and with them I would ask to be permitted to place (and I speak not without the justification of carefully-collected evidence) a large number of cases of crippling rheumatism, almost all of which are known as spondylitis deformans, the great majority of the cases of gonorrhoeal rheumatism, most of the severe forms of neuralgia occurring to young persons, and many peculiar liabilities to hæmorrhage. It seems, indeed, under the ordinary customs of English society, very difficult, even after several generations of strict temperance, to get rid of the gouty diathesis, and some facts would dispose us to the belief that, even after it has ceased, perhaps, during several generations, to manifest itself in the typical form of joint disease, its effects may still be encountered in predisposing to disease of blood-vessels of the kidney and of the nervous system. The facts regarding leprosy are probably somewhat different, but some allowance must perhaps be made for the circumstance that we have not as yet had an opportunity of examining them so critically. It would appear to be far easier to produce leprosy *de novo* than it is to produce gout, and it appears also, as might be expected from this fact, to die out of the system and out of the race much more quickly than does gout. Probably it is associated with some much more definitely specialised dietetic poison than that which causes gout. For, if the hypotheses which I advocated before you two years ago, and which I believe with increasing firmness, to be correct, it is certain that the leprosy poison is capable of considerable concentration under favourable circumstances, and may produce its effects in a comparatively short space of time. Many cases might be cited in which children or adults of healthy English families residing for a few years in a leprosy district, and eating only the ordinary food of the place, had become its subjects. Even in these, however, the malady is never rapidly developed. It always comes on slowly, and not unfrequently does not reach its height until possibly several years have elapsed after removal from the place where it was acquired and return to English food. This development of leprosy without possibility of hereditary transmission, and after short periods of residence in dangerous localities, is, I believe, never witnessed in temperate regions, and never excepting when it is well-known that unwholesome varieties of fish are met with, and where also the wholesome kinds are liable to rapid decomposition. The fish theory assumes that, under such conditions, the special leprosy poison may be taken in very efficient quantities in connection with a very small allowance of fish. It is the quality of the fish, and not its quantity, that we must regard. Next I stop to note that the same fact is observed, though not to the same extent, in the case of the beverages which produce gout. I am especially anxious to draw attention to this statement, because it is almost always forgotten or ignored by those writers who still disbelieve in the fish hypothesis. As

regards my suggestion that the leprosy diathesis is not only more easily produced than that of gout, but dies out more quickly when the cause is removed, many interesting facts might be mentioned. Almost all authorities on the disease have laid stress upon its hereditary tendencies, but a great fallacy underlies all those observations that these supposed tendencies have been witnessed in districts where the original cause—supposing the cause to have been a poison taken in connection with fish—was still in existence. Thus, it is easily possible that the inherited tendency may have been, at any rate, recruited from time to time by the original poison. The careful observations of Norwegian physicians in the United States have proved that leprosy does not persist in the families of immigrants from the leprosy districts of their native land, and have further, I think, made it probable—although I do not know of any special cases that have been published in proof—that even the subjects themselves of leprosy get well after a long residence in their adopted country. I had the pleasure of producing before you, at the time of the lecture to which I have referred, an old lady who had, under my own observation during a period of about three years, recovered from leprosy. She had contracted the disease in Barbadoes, and had recovered in England. She is still alive and in good health, and has now had no sign of leprosy for many years. This was the first case of definite recovery from a severe and characteristic form with which, at the time of my lecture, I was acquainted. Since then, however, two other examples of recovery from leprosy—or, at any rate, a cessation of all leprosy processes—have come under my observation. The subject of one of these, a distinguished missionary, now an old man, is blind and crippled in all his extremities in consequence of leprosy contracted in Jamaica thirty years ago. He has lived the greater part of this time in Canada, and for many years has been quite free from leprosy manifestations. I did not see him when the disease was extant, but the conditions which it has left justify the diagnosis, even if it had not been placed beyond all doubt by the fact that it was made by Dr. Brown-Séquard. Probably there are a great many persons living who are examples of the entire cessation of leprosy processes after long periods of residence in healthy districts; but no particular interest appears as yet to have been attracted to the search for them, and as the process of one recovery is one which extends over such a long period of time, it is not always easy to recover data which place the original diagnosis beyond doubt. Before leaving the subject of leprosy I must briefly summarise the evidence anew which leads me to place it very confidently amongst the diet diatheses. It is the same in all countries, and probably has been so in all ages. It is the same in rich and poor, in hot climates, and in cold climates. It is certainly neither infectious nor contagious; yet it is capable of origination in those who go to reside where it is rife. It slowly gets well in those who leave its haunts and reside elsewhere. It is not possible to mention any climatic condition which is common to all the very varied localities where leprosy is found. Whenever it occurs in a temperate climate it happens to those who are engaged in the fishing trade, and who live, to a very large extent upon the poorer kinds of fish. Although when it occurs in hot climates it usually observes the same rule, yet it now and then happens to those who eat but little fish. But this is always under circumstances where fish is known to be bad, and where it rapidly decomposes. Finally, in all temperate climates leprosy disappears before advancing civilisation, the introduction of agriculture, and the increase of population. Before we can decide as to whether scrofula should rank as in the main a diathesis which is due to defective food, we have to ask what is meant by the term. In answering this question, as well as several other matters which I shall mention, I am glad to acknowledge help from the valuable lecture on this subject delivered before us last summer by my colleague Mr. Treves. The general tendency of modern investigation would seem to be to associate tuberculosis with scrofula, and to teach that both may be, and usually are, the consequences of inflammatory action in predisposed individuals. Much that is known as scrofulous probably never reaches a distinctly tuberculous condition. But the name is still, I submit, appropriately applied if the inflammatory action can be shown to be of the type which often or usually results in a deposit of crude tubercle. On the other hand, there are certain cases in which the proclivity to tubercu-

lois is so strong that it does not wait for the advent of an inflammatory exciting cause, but is produced as a lymphatic neoplasm without the occurrence of preceding congestion. In the very large majority, however, of tuberculous and scrofulous cases a predisposing cause and an exciting cause are both present, the former being an inherited proclivity, the latter an injury, a catarrh, or any influence likely to produce local congestion.

(To be continued.)

THE TEACHINGS OF TWO HUNDRED AND FIFTY YEARS OF SMALL-POX IN LONDON—FROM 1629 TO 1880. (a)

By WILLIAM A. GUY, M.B. Cantab., F.R.C.P., F.R.S.,
One of the Hon. Presidents of the Statistical Society, Consulting
Physician to King's College Hospital, &c., &c.

INTRODUCTORY.—My prime object in writing this paper is to throw light on the important epidemic—small pox—and I provide a sort of side-light by treating measles in the same way. I also place side by side with the Returns relating to these two diseases the deaths from all causes, and the calculated ratios of deaths by small pox and measles respectively to 1,000 deaths from all causes. The ratios so obtained are the materials with which I work. How I came to take this matter in hand, from what sources I got my figures, what breaks or interruptions they are subject to, what the word *Flox*, associated with small-pox in the returns of the 17th century, means, and my reasons for attaching importance to the facts and calculations I have brought together in the first table of the Appendix; these matters form the subjects of what I may call my introduction.

The first subjects of which I treat in the body of my paper, are: the number, magnitude, and frequency of small pox epidemics.

1. *The number of the epidemics* must needs be determined by the meaning we attach to the term epidemic. In the case of small pox, I give my reasons for choosing 100 deaths by small pox compared to 1,000 by all causes, or 10 per cent., and I name that ratio an epidemic. Later on I select 20 in the 1,000 for measles, and 25 per 1,000 for whooping cough, and I make them the epidemic standards for those two diseases.

The small pox epidemic, then, being taken at 10 per cent. I show that there were about twenty such epidemics in the 17th century to thirty-two in the same number of years of the 18th; but not one in the 19th. This, the entire absence of epidemics in this century, "is the salient and notable fact which my inquiries up to this point establish." This conclusion is not weakened, but strengthened, if I substitute other figures, say 50, 75, and 150 for 100. The word epidemic is, in fact, immaterial. The figures will do as well. I may add that it is only in the 18th century, and only four times in it that the deaths by small pox reach or exceed the high figure of 150 in the 1,000 from all causes.

2. Next as to the extreme figures—the *maxima* and *minima*.

The *maxima* too, are most numerous in the 18th century. In that century, and in that only, do we encounter such figures as 155, 169, 173, 184, the highest figures in the present century being, in round numbers, 96 and 98. I may add that all these high figures (155, 169, 173, and 184), occur in the last half of the 18th century, from the year 1752 onwards.

So much for the *highest* figures. Now as to the *lowest*. The *minima* do not fall so low in the 18th as in the 17th and 19th centuries. All the figures, then, point to the 18th century as that of the highest mortality from small pox.

On the other hand, the century, *par excellence*, of the *minima* is the 19th. There is no exception to this statement; for it is interesting to observe that the lowest

figures that occurred in the 17th century, viz., 6·73 and 2·98, stand opposite the two years which have fixed themselves in our memories as the years of the Great Plague, and of the Great Fire, 1665 and 1666. The Great Plague, with its immense destruction of life, and scattering of the population brought the ratio down to 6·73: the Great Fire following fast upon it, reduced it to the still lower figure, 2·98. But no less than twelve times in the 19th century did the minimum fall below the figure of the Great Plague of London, and three times, and those successive years, below the figure of the year of the Great Fire.

If we set aside these two truly exceptional years of the 17th century, the years of the Great Plague and the Great Fire, the least figure, that of the year 1647, becomes 10·08. In the eight years from 1629 to 1636 we also encounter low figures, and once a high one (125).

But the fact stands out in bold relief that whereas, with the exceptions I have indicated, no year in the forty from 1647 to 1686 shows a lower figure than 10·08, and the whole 18th century no figure lower than 15·32, the 19th century displays figures falling as low as, I here use round numbers, 9 (four times), 8 (three times), 7 (once), 6 (once), 5 (three times), 4 (three times), 3 (three times), and 1 (also three times). These are round numbers. I will give you the exact figures for the three lowest. They are—1·49, 0·74, 0·56!

0·56, the lowest figure of the 19th century, is also by far the lowest in the three centuries. It is, roughly speaking, a twentieth part of the least figure of the forty years of the 17th century, a thirtieth part of the minimum of the 18th.

3. Next as to the *frequency* of the epidemics of small pox. Taking still 10 per cent. as the measure and mark of an epidemic, I may state, in round numbers, that they occurred once in two years in the 18th, once in four years in the 17th, and not once in the 19th. Twice only in this 19th century, once in the first thirty years, once in the last forty, was this high, but by no means extreme, figure of 10 per cent. approached. It was in the year 1805, when the figure was 95·92 (in round numbers 96), and in the year 1771, when the figure was 98·37 (in round numbers, 98).

Two more facts are worth noting. It is only in the 18th century that epidemics of the standard of 10 per cent. have lasted more than one year. Twice they continued two years, once four.

The other fact is that if in the 15th and 18th centuries the same figures for deaths from all causes occur, the contingent of deaths by small pox is higher in the 18th than in the 17th century.

This ends what I have to say at present about small pox. It is enough to excite interest and stimulate curiosity.

I shall remind you of some of the results arrived at up to this point, if I now explain and comment upon, the curves which I have had prepared. They all have reference to small pox. (a)

Measles.—With the leading facts relating to small pox fresh in your memories, I now invite you to consider with me the case of measles.

I caused the figures relating to measles to be abstracted, and the ratios to be calculated, because I thought it likely that, being like small pox a disease not hard even for the female searchers of the 17th and 18th centuries to identify, it might yield results which would throw light on my main topic of inquiry, small pox, and I have not been disappointed. The figures show that deaths from all causes have reached a higher level in the 19th century than in the 18th, the exact reverse of what has happened with small pox.

Whooping cough.—The same is true of whooping cough, in reference to which I am able to compare forty years of

the 18th century with seventy-two of this, the 19th. The ratios of deaths by this disease to deaths by all causes, have increased, as did those of measles, during the present century.

I devote the remainder of this paper to a consideration of the bearing of my facts, and the inferences I have drawn from them on the two questions, of the effects of *Inoculation* on the mortality of small pox in the 18th century, and of vaccination on the mortality of small pox during the 19th. 1. And first of *Inoculation*. Now, inoculation, according to the degree of care and skill brought to bear by those who practised it, reduced, often very largely indeed, the rate of mortality due to the disease caught in the natural way. But it created in every person operated upon a new centre from which infection might spread, and doubtless did spread, to the unprotected. Now, what was the result of the simultaneous action of these two forces? Did deaths by small pox increase in the 18th century during which inoculation was being practised? Did they increase in that portion of the century when the practice prevailed, and if so, was the increase of mortality in some sort of proportion to the number inoculated; or was it otherwise? Opinions were divided. Some, with Sir Gilbert Blane, thought that on the whole, inoculation had done more harm by spreading the disease, than good by mitigating it. Others, with Dr. Gregory, a man of large experience in this matter, thought that, on the whole, it had saved more lives than it had wrecked. As to the first question relating to the whole 18th century, I take that to be already answered as far as figures can supply an answer. Small pox was certainly more fatal in the 18th than in the 17th century, and also more fatal than in the 19th, when vaccination has taken the place which inoculation held.

But inoculation was not practised to an extent to influence the death-rate till the end of the first quarter of the 18th century, after which period, it first slowly, then rapidly, came into vogue. Now, if we begin by comparing the four quarters of the 18th century with each other, we find (I will not here trouble you with figures), that the first two quarters, test them as we will, were much less fatal than the last two. The intervals of freedom were longer, the epidemics only half as numerous, and never extending over more than one year at a time; whilst all these features were reversed in the last two quarters of the century. The last half of the century was the period of greatest fatality. *Inoculation* may have been the cause of the difference. Dr. Gregory, as I have said, thought, on the whole, that inoculation had mitigated small pox—had lessened the number of its victims—and he justified himself by figures. In this view I agreed (a) with Dr. Gregory, using, as I did, a different classification of the years of the century, but arriving at similar results. My figures and calculations show an ultimate saving of 5,433 lives. If these figures appear inconsistent with what I have said of the increased severity of the epidemics of the last half of the century, the explanation will be found in the fact that the minimum numbers fell, while the maxima rose.

I must here point out, as forces tending to mitigation, the progressive rooting out of small pox from one of its centres of distribution (our prisons) during the last quarter of the century, and towards the end of it the abstraction of many thousands of possible male victims in the form of recruits to our land and sea forces.

Taking all things fairly into account, I arrive at the conclusion, "that the practice of inoculation by saving a large number of lives among those on whom it was brought to bear, did in a great degree counteract the currency given to small pox among those whom it left alone."

2. *Vaccination*.—And now I treat of *vaccination*—raising, and trying to answer, the simple question—has vaccination, as actually practised during this 19th century in which we are living, reduced the mortality from small

pox? Has it really acted as a preventive? In answering this question I shall first make use of the figures and ratios I have already employed, and then bring into play certain calculations of the Registrar-General, in which he compares the deaths by our leading epidemics (small pox of course included), with the living population. To avoid any slight embarrassment that might arise from the use of decimal points, I shall henceforth use only round numbers. I shall compare the deaths by small pox to 100,000 death from all causes, and then the deaths by small pox to 100,000 persons living. The first comparison of deaths to deaths is peculiarly applicable to the first thirty-one years of the century, the second to the last forty years. For during the first period of thirty-one years, the annual returns were made after the method prevalent in the two previous centuries. They were the old bills of mortality carried forward. Whereas the calculations of the last forty years are those of our new and improved system of registration as issued by the Registrar-General. I am glad to be able so far to substitute his figures for my own.

I will preface what I have to say directly about vaccination by stating briefly the facts already established.

The first fact (and it is a very significant one), is the entire absence from the records of this century of epidemics of the intensity represented by 100 deaths from small pox to 1,000 by all causes, though such epidemics were very frequent in the last half of the 18th century, and one such occurred in the year 1800.

The second point deserving notice is the marked excess of these epidemics in the 18th century when compared with the 17th, and of other indications of increased severity, from which we infer that this most formidable malady had been shorn of none of its terrors by the lapse of time, or even by the great sanitary improvements brought to bear on the Devonshire colic, the scurvy, and the jail fever.

The third point that I notice is the low figures to which the minima had fallen in this 19th century, and especially the lowest of all (56 per 100,000), which so soon followed on what we must now consider the epidemic of 1871.

The fourth point on which I insist, is the contrast to small pox afforded by measles and whooping cough. These diseases became more severe as small pox became less so. Hence, we may infer that some force or forces which did not affect those two diseases did affect this.

(To be continued.)

RETRO-UTERINE HÆMATOCELE.

A Clinical Lecture

By Prof. C. BRAUN VON FERNWALD, of Vienna.

Abstracted and Translated from the *Wien. Med. Zeitung*.

By Dr. J. E. BURTON,

Physician-Accoucheur to the Lying-in Hospital, Liverpool.

SINCE the time of Nélaton has been understood by this expression a collection of blood in Douglas's space, which is supposed to arise by the menstrual blood being emptied into the peritoneal cavity instead of into the uterus. Known to the elders under the name of *suppressio mensium*, this affection, which is often dangerous to life, is deserving of the greatest interest, as it is one that may offer itself for treatment in the practice of any physician. Parametritic exudation and extravasation of blood into the peritoneal cavity are mostly met with in sterile women, and such as have not borne offspring for a lengthened period. Two forms are distinguished, intra and extra-peritoneal hæmatoceles, of which the former are much more frequent. In opposition to the opinion of French observers, hæmatoceles must not always be associated with extra-uterine pregnancy; but as this frequently is the case, the breasts should always be examined for milk, and the genitals for the blue colouration indicative of pregnancy. A positive condition may here be determined with tolerable ease, but

(a) See "Public Health," p. 105.

the determining of one that is merely negative is often difficult; for instance, that the hæmatocele in a given case is not dependent on extra-uterine pregnancy.

In proof of this, Prof. Braun related a case in which he was consulted by a "homoeopath." The patient was prostrated by violent abdominal pains, and she had a tolerably large elastic tumour in the lower part of the abdomen, concerning which he expressed the opinion that, in case it merely retained its size, or actually became smaller, it would prove to be a blood extravasation; if, on the other hand, it increased in volume, it would prove to be an extra-uterine pregnancy. The physician in charge would not admit the second possibility, on the ground that the husband had been impotent for ten years, and that the wife was of a respectable family. Notwithstanding this the tumour gradually increased in size, and in a month's time colostrum could be pressed out from the nipples. The patient's condition became rapidly worse. The Professor was once more called in, but could do no more than pronounce the case hopeless. Death took place from hæmorrhage into the peritoneal cavity from rupture of a blood-vessel whilst the patient was in a hot-bath.

Examination *post mortem* revealed the fact that extra-uterine pregnancy existed, and, moreover, that the pregnancy was double; there were twins.

Hæmatocele is indicated by the following symptoms:—Menstruation is generally painful, accompanied by malaise and shiverings; frequently the menstruation ceases suddenly. The patient suffers from shock, and in consequence of the internal hæmorrhage the skin and mucous membrane become blanched. If the course of the affection be unfavourable the patient becomes collapsed, the tumour presses upon the bladder, the ureters become sharply flexed, and death supervenes. If, on the other hand, the course be favourable, the extravasation becomes encapsuled, and an elastic tumour is then to be felt with ease, both from the vagina and from the rectum. The folds of Douglas are in no other disease depressed so much as in hæmatocele and extra-uterine pregnancy. The two affections cannot, however, be distinguished one from the other for the first three months—three months after the cessation of the menses—and it is only afterwards that the slow growth of the tumour allows the conclusion to be drawn that the case is one of abdominal pregnancy.

For the differential diagnosis of retro-uterine hæmatocele from ovarian cyst Prof. Braun notes the following:—First, the contour of a hæmatocele is not sharply defined on its upper border. Second, notwithstanding its fluid contents, it always gives a tympanitic sound on percussion, for the reason that the coils of intestine, in consequence of the peritonitis that accompanies every case of hæmatocele, are intimately united to it. Both these peculiarities are absent in ovarian cysts.

The treatment consists in absolute rest in bed, prohibition of cohabitation, application of ice to abdomen, and enemata of cold water. Care must be taken that the bowels and bladder are properly relieved, and if there are no grave complications, resorption of the blood will bring about recovery within three or four weeks. In severe cases, in which fever and pain are very persistent, and there is reason to fear the rupture of a possible abscess into the abdominal cavity, the tumour should be punctured through the vagina as recommended by Nélaton. If there is any suspicion of extra-uterine pregnancy, however, Prof. Braun would caution against puncturing, as it might easily set up profuse suppuration, to which the patient might eventually succumb.

WE regret to announce the death of Mr. J. P. Crosby, L.R.C.P.Ed., medical officer of the Sunderland Workhouse, from an overdose of morphia. It appears the deceased had been accustomed to resort to the use of the drug as a remedy for sleeplessness.

Clinical Records.

LIVERPOOL INFIRMARY FOR CHILDREN.

A Case of Old Hydatid Cyst of the Liver, cured by Incision and Drainage.

Under the care of Drs. OXLEY and POLLARD.

Reported by Mr. P. DAVIDSON, M.B., C.M., House Surgeon.

ELLEN R., æt. 9, was admitted into the Children's Infirmary, Liverpool, on October 10th, 1880, under the care of Dr. Oxley, complaining of a tumour in the abdomen in the site of the liver, which was painful if pressed on.

Previous History.—She had been in the infirmary two years previously, when the tumour was tapped, and clear fluid drawn off containing echinococci. She had then been dismissed as cured, but gradually the swelling had reappeared.

State on Admission.—On admission there was a distinct fulness to be observed in the right hypochondriac region, which on palpation gave a sensation of deep fluctuation, and was tender on pressure. The margin of the liver could be felt about the level of the umbilicus to be thin and sharp. No hydatid thrill could be felt. The tumour was dull on percussion.

October 20th.—A Southey's trocar and canula, with india-rubber tube attached, were inserted into the most prominent part of the tumour, and 8½ ozs. of turbid yellow fluid drawn off. The fluid was full of albumen and pigment matter. No bile pigment could be detected, and no echinococci could be seen.

The patient was ordered tr. aconiti ℥ v., tr. opii ℥ iv., every four hours.

21st.—No bad symptoms followed the tapping. The swelling had disappeared. The margin of the liver remained at the same level.

31st.—The cyst having refilled, was again tapped with a Southey's tube, and 7½ ozs. of fluid drawn off in fifteen minutes.

November 11th.—Two Southey's canulas were inserted, and left in for two hours. After the fluid had been drawn off a quantity of thick, yellow material drained through the tube, which, on examination through the microscope, was found to contain large quantities of yellow pigment, and numerous detached echinococci filled with pigment, many of them partially broken up.

The cyst having refilled, a Southey's tube was again introduced, and left in for 48 hours, with the view of establishing a sinus, but having become displaced, owing to retraction of the liver when the cyst had emptied, it was withdrawn.

The case then, owing to Dr. Oxley's illness, passed under the care of Dr. Pollard.

December 14th.—A hydrocele trocar and canula were introduced into the cyst under the antiseptic spray, and 5½ ozs. of fluid withdrawn. The canula was left in, and a carbolic gauze dressing applied.

At this time the patient had an attack of tonsillitis. There was no inflammation about the wound, and no general abdominal tenderness.

17th.—The canula was removed.

29th.—The sinus had healed up.

February 12th.—The cyst was again tapped with a hydrocele canula.

20th.—The cyst having refilled, it was determined to cut into it and introduce a drainage tube. In order to ensure thorough adhesion of the liver to the peritoneum at the site of the tumour, Dr. Pollard made a incision one inch in length over the most prominent part, carrying it down to the peritoneum. He then pushed two trocars and canulas into the cyst, one at each end of the incision. After withdrawing the trocars, the wound was plugged with salicylic silk, leaving the canulas *in situ*.

March 5th.—The canulas were withdrawn, the sinuses united by an incision, and a large drainage tube introduced into the cyst.

A dressing of carbolic gauze and salicylic silk was applied.

9th.—The discharge had become mixed with pus, but remained quite sweet. Temp. normal. The cyst was syringed out daily with 1 to 60 carbolic lotion.

12th.—The membrane lining the cyst wall came away entire on syringing the cyst.

20th.—Contraction of the cyst took place gradually, the drainage tube being pushed out bit by bit.

April 2nd.—A horse-hair drain was substituted for the india-rubber tube.

9th.—The horse-hair drain was withdrawn.

19th.—The sinus had completely healed up, and the patient was discharged.

June 5th.—The patient was examined. There was no re-appearance of the tumour, no tenderness on pressure. The margin of the liver could still be felt at the level of the umbilicus. The patient was in good health.

CASE OF SLIGHT POISONING FROM THE EXTERNAL APPLICATION OF ATROPIA.

Under the care of ALEX. W. WALLACE, M.D. Ed.,

Medical Officer of Riverstown Dispensary District.

A GENTLEMAN, æt. 70, when drawing on his boot, was suddenly seized with pain referred to a spot at the origin of some of the fibres of the gluteus muscle. No chloroform or belladonna being at hand, I ordered the following:—Atropia gr. iv., chloroform, tinct. aconite (Fleming's), aa ʒij. I poured about half a drachm of this on a piece of spongio piline, and placed it over the painful spot, the skin being quite sound. In about an hour he drove in to my house in great alarm, believing he had got an attack of paralysis. The pupils were dilated, voice very weak, and speech mumbling. Mouth very dry, and a feeling of inability to raise the legs. Next day he wrote: "The symptoms continued, I may say, till bed-time; speech thick and rambling; memory nearly gone; feet seeming not to belong to me, like lumps of lead; also great irritation of urinary organs." The last symptom, I presume, was due to spasm of the sphincter of the bladder, which Sidney Ringer says has been noted in cases of belladonna poisoning, and which I can testify from personal experience is produced by doses of about 1.25th of a grain of atropia, the only other sensible effect being dryness of the mouth. I may say that the pain for which the atropia was used in the above case was greatly relieved by it, only the cure was considered worse than the disease.

The Mineral Waters of Europe.

THE "MEDICAL PRESS"

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.
President of the Pharmaceutical Society of Ireland, Lecturer on Chemistry, Carmichael College of Medicine, &c.

WITH

NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.
Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 50.)

Liquor Magnesiæ Carbonatis (Fluid Magnesia).

THIS preparation, although not generally classed as a mineral aerated water, will, on a little consideration, be seen to be made upon the same lines. It was originally introduced to the profession by a well-known physician in his day, Sir James Murray, of Dublin. He brought it out as a patent, or proprietary medicine, many years ago. After gaining great popularity under the name of fluid magnesia, its celebrity rather declined, owing to the fact that it deposited crystals of magnesium carbonate. The original preparation was made by suspending carbonate of magnesia in water in a tub, or suitable vessel, and passing carbonic acid gas through it until it dissolved. The solution was then allowed to settle, and the clear supernatant fluid poured or drawn off for use. As thus made, it contained a very little excess of gas, and therefore soon deposited the crystals of magnesium carbonate. Sir James Murray, many

years after its first introduction, patented a fresh process, by which, after pouring off the bright fluid, it was re-aerated under considerable pressure. This seems to be the process of the Pharmacopœia. In that book we are directed to make a moist carbonate of magnesium by precipitating Epsom salts with carbonate of soda, and then to pass an excess of carbonic acid gas through it for 24 hours. The resulting fluid is directed to be filtered, and then re-charged with gas. It will be seen that such a process amounts to the production of an aerated water, and is, in fact, Sir James Murray's patented re-carbonated process.

As the fluid magnesia is in the hands of two or three manufacturers of acknowledged celebrity, we generally get the right thing. It might be more strongly aerated, however. It should contain 13 grains to the fluid ounce. The strength could be reduced to 10 grains with advantage, and would make a more permanent preparation.

Liquor Potassæ Effervescens (Kali Water.)

A valuable water, containing, according to the Pharmacopœia, 30 grains to the pint of bicarbonate of potassium. Although so easily made, it has been found very varying in quality. Kali water is not much used, and is probably made carelessly by the manufacturer. As it is one of the most active of the antacid waters, it should be of a uniform strength. We never recollect having examined, however, any kali water that did not contain something near the quantity.

Soda Water.

Soda, of all the aerated waters, is the most generally consumed, and, therefore, may be considered the most important. There are certain requirements which must be met, and the desire for a well-marked antacid and carbonated drink is hit off in soda water. Soda is perhaps naturally selected by the stomach, and probably with advantage, as it is the alkali which of all others is least likely to derange the animal system. The large amount of that substance in the human body, which may be roughly calculated at 0.5 per cent. of all the fluid constituents, could not be much influenced even by the constant use of soda water.

Liquor Sodæ Effervescens, the soda water of the Pharmacopœia, is rather a strong preparation, being 30 grains to the pint. If we might judge of the results from what we find in commerce, it is considered too strong, for in no case could you get anything approaching this strength. Instead of 30 grains we find the most erratic confusion upon the subject of soda water. A few selected analyses of samples analysed will illustrate this more aptly than any discourse upon our part.

Grains p
10 oz., or ½ pint.

- | | |
|---|-----|
| A. B.P., from a respectable manufacturer sending it out under that brand ... | 15½ |
| B. No sodium bicarbonate was present in this sample, it being aerated water, and the solid proceedings from the water used (chiefly lime salts) ... | 3½ |
| C. Sulphate of sodium, 10; bicarbonate of sodium, none ... | 10 |
| D. Sulphate of sodium, 5; bicarbonate of sodium, 4 ... | 9 |
| E. Bicarbonate of sodium ... | 5 |

The use of sulphate of sodium is peculiar, and although such a preparation may be called a "soda water," it is not what is generally accepted as the ordinary effervescent preparation which goes under that name. We presume that a certain class of drinkers, when they require an early morning draught, wish for something more aperient than the antacid liq. sodæ effervescens of the Pharmacopœia. In the sample "D" we find the two judiciously blended, whilst in "B" it is probable that the water was too hard to allow of the use of bicarbonate of soda. "E" is a striking example of the uncertainty of strength found amongst the commercial preparations. Some houses send out as many as five strengths.

I find the B.P. preparation is like all waters which contain a considerable excess of soda, a little "soapy" in its taste, and it is just probable that this is one of the causes which induce the manufacturer to diverge from the recognised standard.

The general divergence observed in an article which is supposed to have a definite preparation, and which is frequently recommended by the physicians, is disgraceful in the extreme, and certainly something should be done to regulate the chaos exhibited by this preparation. Every manufacturer should definitely state upon the label the amount of sodium bicarbonate contained in his preparation.

Carrara Water,

So named from the springs in the marble district of North Italy, is now understood to be a saturated solution of carbonate of calcium in aerated water. There is hardly any demand for this water, therefore it calls for no remark.

The most important point about artificial mineral waters, however, is the quality of the water from which they are manufactured. We have no doubt that a large manufacturer's important considerations are—first, is my water pure? secondly, is it sufficiently soft to enable me to use it with advantage? This is as it should be; but we have to take into consideration that at the present day in almost every unimportant town there is a local man who starts to manufacture mineral waters because the circumstances call for his action, and because "it pays," in nine of such cases out of ten he becomes a disseminator of poisonous water—sometimes so bad that the flavouring material alone hides a quality which in its impure, but simple state would be unbearable.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

INTER-CRICOIDAL LARYNGOTOMY OVER TRACHEOTOMY.—At the Société de Chirurgie a discussion arose on the advantages of inter-cricoid laryngotomy over tracheotomy. The discussion originated in a communication by M. Richelot relative to this operation, which he practised on a man who presented a vast epithelioma of the floor of the mouth, and insisted on the facility of the operation as compared with that of tracheotomy. According to him the dimensions of the cricothyroid space are perfectly sufficient to introduce the canula, which, however, should be of small dimensions, for a large tube would be difficult to introduce, and further, might

burst the cricoid cartilage. M. Nicaise, who took up the defence of this method, said that he had performed laryngotomy on a man of 67 years of age for cancer of the larynx, and it succeeded very well. M. Chauvel preferred tracheotomy, for the tube must be necessarily too small. M. Desprès declared himself an adversary of the operation in question, for the efforts of deglutition caused the tube to rub constantly against the walls of the larynx, and thus inconvenienced the patient rather seriously. M. Verneuil, on the contrary, considered laryngotomy an excellent operation, easy to perform, and deprived of those dangers which attended tracheotomy. In some cases it is even the only one possible. He had actually a patient in his service on whom he performed this operation for epithelioma of the pharynx, and having introduced the tube of Krishaber, the man speaks and eats well. Another member declared that from experiments on the dead body he found that laryngotomy was much easier to do than tracheotomy. The discussion ended with M. Launelougue, who maintained that tracheotomy was ordinarily a difficult operation, and often dangerous, and he certainly preferred to replace it by laryngotomy.

TREATMENT OF HEREDITARY INFANTILE SYPHILIS.—M. Archambault, of the Hôpital des Enfants Malades, prefers in the treatment of hereditary infantile syphilis the corrosive sublimate to calomel or hydrargyrum c. creta. He administers the 25th of a grain in the 24 hours in milk or water. By degrees the dose is brought up to one-tenth of a grain, which represents the maximum. As salivation was not found in children, the mercury should be suspended when the mucous patches commence to disappear, the ulcers to fill up, &c. It was said that the mercurial treatment provoked diarrhoea, but such was not his experience. Where the syphilis was slight, frictions with the mercurial ointment often suffice. As to baths of sublimate, he had used them with good effect, especially against the cutaneous manifestations of the disease. The dose would be from 30 to 40 grains for each bath, and if a metallic bath be used, half an ounce of hydrochlorate of ammonia should be added to prevent the decomposition of the mercury in the presence of the metal.

WASHING OF THE STOMACH has been employed for some years with a certain success in several affections of this organ. The mode of operation, with the indications and results, are comparatively well known. However, up to the present the operation has been mostly confined to hospital practice, as medical men in private practice hesitate to employ it, believing that it is rather too delicate to undertake the responsibility of it. M. Faucher has invented an instrument which makes the operation just as easy as that of washing out the bladder. The instrument consists of a tube of red caoutchouc, called English caoutchouc, very smooth and supple, of about four feet in length, and having a diameter of ten millimetres. At the free extremity the tube is pierced by two holes or eyes, while the other end is adapted to a funnel of glass or metal. To perform the operation (*lavage*) the patient introduces as far back as possible the free end of the tube, which is previously moistened, until the pharynx is reached, when by movements of deglutition it is carried down the œsophagus until it reaches the stomach. A mark on the tube placed about eighteen inches from its extremity announces its arrival. As soon as the tube is introduced the patient fills the funnel and raises it above his head. The liquid descends, and when the vessel is almost empty it is lowered rapidly on a level with the stomach, and all the liquid returns, mixed with the residue of digestion. After several applications the patients learn to handle the instrument with the greatest facility, and without experiencing any nausea. The liquid employed usually is water with a little

bicarbonate of soda; antiseptic agents, however, might be used, such as chloral, borax, &c. The temperature of the liquid should be cold. Disease of the mucous membrane of the stomach, catarrh, primitive or secondary, simple ulcer, alcoholic gastritis, &c., furnish indications for the operation. Cancer has been palliated by it, and in cases of poisoning it has been valuable.

HYPDERMIC INJECTION IN CHOREA.—Commenting on the case of chorea treated by hypodermic injection of Fowler's solution contained in my letter of the 3rd May, you justly draw attention to the large dose (40 drops) that M. Gagnon, of Clermont, injected at the one time. Thinking that the French preparation might be weaker than the English solution, I have compared them both, and find the contrary to be the case, as you may see:—

English.	French.
Arsenious acid, 80 grains.	Arsenious acid, 90 grains.
Carbonate of potash, 80 grains.	Carbonate of potash, 90 grs.
Tinct. lavand. co., 5 drachms.	Water, 16½ ounces.
Water, 20 ounces.	Alcohol, ½ ounce.
4 grains to the ounce.	5½ grains to the ounce.

I will try to obtain more ample information on the subject, but M. Gagnon, in an article written under his dictation, affirms that the dose mentioned has not been attended with any bad results in his hands.

CONVULSIONS IN CHILDREN.—M. Jules Simon prescribes the following enema for convulsions in children, when the patient cannot swallow:—Musk, 4 grains; chloral, 6 grains; camphor, 15 grains; yellow of one egg; water, 6 ounces. A simple injection is previously made to remove any matter that might prevent the effect of the enema.

Special.

THE INDIAN MEDICAL SERVICE DEFENCE COMMITTEE.

THE Indian Medical Service Defence Committee has again addressed a remonstrance to the Secretary of State for India. They represent that by the Royal Warrant of the 13th of January, 1860, a rule was introduced rendering retirement compulsory for administrative officers at the age of 65, and for executive officers at the age of 55; that the result now is that from 60 to 70 per cent. of the late East India Company's officers remaining in the service are precluded from that promotion to which when they entered the service they were taught to look forward with perfect confidence. By the Royal Warrant of the 10th of May, 1873, the age of superannuation for those executive officers who entered the service before the 13th of January, 1860, was extended to 58, subject to the production of a medical certificate of fitness, and in the Royal Warrant of the 16th of November, 1880, now in force, this privilege has been continued, but the limit of age for administrative officers has been diminished from 65 to 60. An officer promoted under the 58 years' rule will not be permitted to serve his full five years as a qualification for the increased pension of the grade. He would necessarily attain the age of 60 before the expiration of that period, and will be compelled to retire; the three years' extension of the executive age limit will therefore be practically worthless, except in enabling an officer who has had an exceptional amount of leave to complete the term of service for the £700 per annum pension.

From tables appended to their document it appears that 73 per cent. of the officers in the Presidencies of Bengal, Madras, and Bombay can never be promoted under the 55 years' rule, and that, under the 58 years' rule, the percentages will be 66, 63, and 65 in the three Presidencies respectively. The more fortunate individuals who obtain promotion will, however, only do so after a very protracted service, averaging nearly 32 years in the former, and 35 years in the latter case, instead of 25 or 26 years, the period which, for many years, has been the usual one. That a period of 26 years' service is a reasonable one for the attainment of administrative rank, the Govern-

ment have themselves practically acknowledged by fixing that period for the exceptional promotion of sanitary officers. They submit that the retardation of promotion in the one case, and the absolute impossibility of promotion in the other, establish, on behalf of the late Hon. East India Company's medical officers, an equitable claim for compensation.

They reiterate their appeal against promoting to administrative rank and privileges certain sanitary commissioners after a fixed period of 26 years' service.

They submit the advisability of assimilating the Indian Medical Service *Invaliding* Pension Scale to that of the Army Medical Department, to which, they say, it is now slightly inferior. They state that the Indian medical officer, if compelled to retire from ill-health prior to the completion of 15 years' service, obtains the half-pay of his army rank, which is, in the case of a surgeon, £127 15s., and in the case of a surgeon-major, £173 7s. 6d. An Army medical officer, if invalided under five years' service, obtains £109 10s.; if over five years and under ten years, £146; if over ten years and under fifteen, £182 10s.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 26, 1882.

MIDWIVES.

It is a curious reflection that in a country like England we have so long been content to entrust the lives of more than half the pregnant female population to the care of unqualified and uncertified women at a time when, by no improbable chance, circumstances of the utmost danger may arise to render skilful obstetric interference necessary to avert a fatal issue. It is indeed a startling revelation that at least 50 per cent. of children born in this country find their first experience of the world at the hands of women who claim the rank and title of midwife at their own will and pleasure. Of

such self-styled practitioners the number exceeds ten thousand, and at last there seems a likelihood that they will be brought under the influence of authority by which they will be licensed to practise the profession of midwifery, and without the sanction of which the exercise of their calling will be an illegal act. A Bill having for its object to register and control the actions of midwives has been drafted, and has recently been under discussion in the General Medical Council, with results to which we need not further allude. As an act of courtesy, it was, of course, desirable to give the Council an opportunity of expressing an opinion on the measure itself, but equally, of course, no one ever imagined that any practical advantage would accrue from its discussion by the Council.

In connection with the proposed legislation on this matter, a good deal has been said as to the credit of originating it; and it is a little instructive that two eminent members of the Medical Council should have been allotted and have accepted the distinction of initiating discussion on the question some years ago, while, at the moment when their tentative efforts seemed to take on some useful form, they, almost alone, offered opposition to the only legitimate solution of the problem involved in it. While admitting all the evils which it is the object of the Bill to remove, Mr. Simon and Sir Wm. Gull still energetically insist that the Council should adopt a responsibility-shunning attitude, and *approve* principles, but decline action. Such conduct would better besem an assembly of schoolboys; it reflects no credit on those who have been entrusted with the solemn charge of preserving the interests of the medical profession; it partakes of the fatal policy of indecision and of weakness; and it is to be hoped that those who have assumed the burden of reforming the great midwifery abuse will not be influenced to abate one iota of the full and complete programme shadowed forth in the scheme they have published.

Of the necessity for an Act of Parliament of the kind there can be no question in the mind of any one who is familiar with the frightful consequences that ensue from the present practice in this country. As it is, any woman, however ignorant or stupid, is at liberty to assume the responsibilities that attach to an accoucheur. Calling herself a midwife, she can attend those women who will accept her services during the period of labour; and it sometimes, and that not infrequently, happens that in cases of difficult or complicated delivery the most egregious and irrecoverable mistakes are committed, ending in the death of the patient. We cannot form any idea of the amount of mischief these midwives do from the number of prosecutions directed against them for manslaughter and injury. It is only a few of the errors that are thus published, for in most instances one of three courses is pursued by the agents of the disaster whereby they preserve themselves from the consequences of their blunders. Thus, by calling in the services of a medical man, they shield themselves behind him, or even accuse him of bringing about the danger he has been summoned to avert; or they leave the case altogether when they find themselves unable to effect delivery; or,

having inflicted fatal injuries, they decamp from the neighbourhood, and thus render the chance of discovery and prosecution all but impossible. It may very well be asked what reason can exist to induce persons to employ these pretenders, especially since the fees charged by practitioners in thickly-populated districts are even absurdly small. Little though they are, however, they much exceed what a midwife will accept, while, also, they agree to accommodate their clients by receiving the amount in weekly or other instalments. Added to this is the personal influence brought to bear by women on women, and which is oftentimes sufficient to create dislike and distrust of qualified accoucheurs. Nor do the numerous errors committed by midwives seem to act as a warning to the labouring and indigent classes. They continue to employ them, notwithstanding the most complete exposures of inefficiency, electing rather to credit the interposition of "accident" than to believe in the necessity for avoiding the perpetrators of mischief. The nature of these mistakes, too, is of the most terrible kind. Some of the accounts given of cases transferred from midwives to medical men are absolutely appalling. They include not a few in which the uterus has been torn bodily away under the supposition that it was the afterbirth; others in which the most dangerous expedients have been resorted to in order to hasten delivery through unnaturally small pelves, and very often the occurrence of abnormal and difficult presentations is wholly overlooked, the obstructions met with being treated in somewhat rude, though ready fashion, by resort to main force.

That such frightful and general ignorance should prevail among women altogether uneducated for the special work they undertake is no more than would be anticipated. We have again and again, in conversation with ordinary so-called midwives, convinced ourselves of their total ignorance of the barest elements of obstetrical knowledge. It is rarely that they are found to have any conception of the uterus as something more than "a hole in the belly;" the notion of ovaries and their relation to pregnancy is wholly unknown; while the physiology of conception and development is a sealed book to even the best of them. Exceptions, however, to this statement must be made in the case of women certificated by the Obstetrical Society of London; but they are too few in number compared with the great body of individuals to be taken into account in this connection, while they are certainly not more highly educated and practically trained than it is eminently requisite that every midwife must be.

Any Bill, therefore, that provides for the registration of midwives, and enacts that registration shall be accorded only to women who give evidence of the knowledge and ability necessary to enable them to conduct an ordinary labour with success, will have the effect of preserving innumerable lives which, in its absence, are sacrificed to the ignorance of pretenders to midwifery. With the machinery of the Bill we would not stay to deal now. Its provisions will be debated and scheduled by competent and interested persons, and it is enough now to experience the conviction that any measure which checks

the awful waste of life which follows the existing system must be productive of good. Once given a register of midwives, the control of their actions becomes a matter of ease and certainty, with the added assurance that all doubtful cases will receive the immediate attention of a skilled practitioner, since the Act would both insist on a midwife being able to recognise any uncommon case and refuse permission to her to treat it.

THE FUTURE METHOD OF CERTIFYING MEDICAL STUDIES.

THE Irish College of Surgeons has finally adopted and promulgated a most important series of rules having for their object the stamping out of the disgraceful sham certificate system which has been, for so many years, the opprobrium of the Dublin Medical School. The College will in future reject any certificate of a student's which is not issued in conformity with the following regulations:—

1. All lecture certificates shall set forth the exact number of the student's attendances, and the total number of lectures delivered in the course.

2. Winter courses shall consist of not less than 50, and summer courses of not less than 30 lectures; and the certificate must certify an attendance on at least three-fourths of these numbers.

3. As regards hospital certificates, the number of daily attendances certified shall be not less than 80 winter and 40 summer.

4. The attendances of students shall be checked by the following methods:—

5 (a) As regards lectures, that printed cards be issued at intervals by the lecturer or school registrar to each student, and that one of such cards, properly signed and dated by the student, be received by the lecturer from each student when leaving the room after the lecture.

6 (b) As regards hospital attendance, that a book be kept in which each student shall sign his name from day to day; that such book be taken up by one of the medical officers each morning, and be ruled off and signed by him each day, so that no entry may be made therein, except on the particular day indicated by the signature. That in case it appears from the nature of the signatures therein that more than one name has been signed by the one person, the whole of the signatures which appear to be so written shall be struck out by the registrar, and no credit given for the attendance on that day to any of the persons so named. That such book be kept for future inspection.

8. The various courses of medical study required shall be set forth in a "schedule," and

9. The registrar of the schools and surgical hospitals at which the student has attended shall sign a declaration upon such schedule that the entries therein respecting the attendances at their respective school are in all respects correct.

10. The student shall be also required to sign a declaration upon such schedule to the same effect, and furthermore, that he agrees that, if the College licence should, after examination, be granted to him on the faith of the entries in such schedule, the diploma may be cancelled, and the licence withdrawn, if it be afterwards ascertained that the entries are not correct.

We take occasion to express our unqualified admiration of the determination evinced by the Council of the College to "turn over a new leaf" in this matter. We take a little credit to ourselves for having initiated the crusade against sham certificates many years ago, and

carried it on in spite of obloquy and abuse, by a candid exposure of "the tricks of the trade" of medical teaching which had brought down the character of the Dublin School very low indeed.

The Council of the College has shown itself very willing to remedy these abuses when the facts were brought to its knowledge and proved to its satisfaction, and it has thus given to the profession and the public an assurance that it will no longer tolerate the existence of corrupt practices in Irish medical teaching.

THE TEACHING OF PATHOLOGY IN THE UNIVERSITY OF EDINBURGH.

SINCE the year 1831 pathology has been taught in the University in a course of didactic lectures delivered during the winter months; and in the Extra-Mural School a like course has also been given by a lecturer who was at the same time pathologist to the Infirmary, and who had therefore great facilities for teaching his subject both theoretically and practically. The want of material for the practical work of his class has doubtless been keenly felt by the Professor, and it is but natural that he should attempt to fill the present vacant post by the election of his class assistant. From a University point of view this is intelligible enough, but there is the Extra-Mural side of the question also. Even University professors are obliged to admit that the Extra-Mural School is the backbone of the Edinburgh Medical School, and that a flourishing and active Extra-Mural School is necessary, that Edinburgh may maintain its prestige as a great centre of medical education. The post of Pathologist to the Infirmary has, as before mentioned, been always held by a struggling extra-mural lecturer who has been compelled to carry on a competition in which he was handicapped by the fact of the professor being also an examiner, a disadvantage which is daily increasing, owing to the commercial mania now affecting several of the professors. Whilst admitting that the Professor is entitled to access to fresh specimens and other means for practically instructing his class, it certainly does not seem fair to us that either party should possess an undue monopoly, and we would therefore suggest that both the Professor and an Extra-Mural lecturer be appointed, when some amicable arrangement might be entered into between them as to the division of labour. Let the Professor be appointed, and not his class assistant. The squeezing in of a subordinate is not characterised by that manliness and openness which should ever prevail between gentlemen. Besides, the election of the Professor would place a permanent officer in the post, and not a young man who may be only looking out for something "to turn up," or who might at any time qualify for an extra-mural lecturer, leaving the Professor in his present somewhat anomalous position. The emoluments of the post are, we believe, about £100 per annum. This might even be equally divided.

DR. CRICHTON BROWNE and Dr. A. B. GARROD have been elected Corresponding Members of the New York Academy of Medicine.

Notes on Current Topics.

The London Hospital.

ON Tuesday, July 18th, the London Hospital was the scene of an unusually successful and important gathering, the occasion being the annual prize distribution to students and practitioners. H.R.H. the Duke of Cambridge, president of the hospital, performed the ceremony, and among those present were several influential and eminent friends of the institution, including the Bishop of Bedford and Mrs. and Miss Gladstone. The Duke of Cambridge was received at the principal entrance by the members of the house committee and the medical and surgical staff of the hospital, a guard of honour from the 2nd Tower Hamlets Rifle Volunteers being in attendance. After presenting the prizes to the successful students and practitioners, His Royal Highness delivered an address, in which he praised the deservedly high reputation of the hospital as a school of medicine, and in particular dwelt on the great advances it had made within recent years. He offered a few seasonable hints also to the young surgeons before him in reference to service in the Army Medical Department, and complimented them by expressing a wish that the ranks of army surgeons might be recruited by men so well trained and taught in surgery as the students of the London Hospital. After the distribution ceremony, the wards of the hospital and the rooms of the medical school were thrown open to the inspection of visitors, and a selection of music was played in the grounds by the band of the 2nd Tower Hamlets Volunteer Corps. Refreshments were served in tents erected in the gardens, and for some time the scene was one of unusual but delightful animation. The attendance was large, and the whole proceedings passed off with great *éclat*, which result is undoubtedly attributable chiefly to the unceasing exertions to secure it on the part of the Warden of the school and to the hearty seconding of his efforts by the house and college committees. While congratulating them on the success of their endeavours to afford enjoyment to the many friends who were favoured with invitations, we feel that they will be fully repaid in the knowledge they have gained of the wide-spread interest which is felt in the fortunes of the great East-end charity.

The Physiciancy of the Dundrum (Dublin) Criminal Asylum.

WE understand that Dr. Christopher Nixon, Physician to the Mater Misericordiarum Hospital, Dublin, has been appointed by the Lord Lieutenant to the office of Visiting Physician to the Dundrum Central Criminal Asylum, *vice* Dr. John Hughes, recently deceased. We are well satisfied with the appointment which Lord Spencer has made, not only because a physician so deserving has been chosen, but because we apprehended a possible abolition of the office. Many of our readers are aware that for years past a strong tide has been running in favour of the discontinuance of all visiting physicians to Irish asylums. The Irish Lunacy Commissioners have shown themselves favourable to such a project, and some of the resident medical superintendents of Irish district asylums (including

the resident medical superintendent at Dundrum) are known to have been anxious to wipe out the visiting officers. On the other hand, we have always vehemently resisted any and every proposition for handing over these large and important institutions to the semi-responsible charge of a single officer, and we have been supported in our resistance by the frequent occurrence in Irish asylums of irregularities which make it obvious that in such institutions "two heads are better than one." Therefore, we are glad that the abolition policy has failed in this instance, and that a young man who has the energy as well as the competency to discharge his duties as visiting physician has been placed in office.

British Home for Incurables.

THE twenty-first anniversary of the foundation of the British Home for Incurables was celebrated at Clapham Rise last week, on which occasion the Prince and Princess of Wales attended a garden party at the Home. A presentation of friends to the Princess took place on a dais in the gardens, upwards of £350 having been collected in this way. The Prince of Wales delivered a brief address in acknowledging a vote of thanks passed to Her Royal Highness the Princess, in which he urged the claims of the institution to the compassion of the charitable. In connection with the Home, 149 in-patients and 384 out-patients are maintained at present, the latter receiving an annuity of £20 each.

Mr. Thomson's Case of Ligature of the Innominate.

WE regret to learn that the patient whose innominate Mr. Thomson, of the Richmond Hospital, Dublin, tied some weeks ago for subclavian aneurism succumbed on Thursday last in consequence of repeated secondary hæmorrhages. He had lived 42 days after the operation, the longest known period save one during which a patient has survived such an operation.

We understand that, at the post-mortem examination, the artery was found to have been ulcerated at the seat of the ligature. The condition of the aneurism as regards consolidation and cure has not yet been ascertained.

The Naval Medical Staff at Alexandria.

THE following is a correct list of the naval medical officers present at the bombardment. H.M.S. *Invincible*: Staff-Surgeon S. Sweetman, Surgeons O. Pearson and M. Digan; H.M.S. *Alexandra*: Fleet-Surgeon D. M. Shaw, Surgeons J. C. B. Maclean and C. A. Macaulay; H.M.S. *Téméraire*: Staff-Surgeon J. Buckley, Surgeons H. E. F. Cross and W. Tait; H.M.S. *Monarch*: Fleet-Surgeon M. Rodgers, Surgeons W. Brown and McIvor; H.M.S. *Inflexible*: Fleet-Surgeon H. M. N. Sedgwick, Surgeon C. Drake; H.M.S. *Superb*: Fleet-Surgeon D. O'Connor, Surgeons A. R. Joyce and J. A. McAdam; H.M.S. *Sultan*: Fleet-Surgeon G. Mair, Surgeons T. J. Preston and W. Eames; H.M.S. *Condor*: Staff-Surgeon W. H. Putsey; H.M.S. *Cygnets*: Surgeon H. W. D. Walsh; H.M.S. *Decoy*: Surgeon F. Williamson; H.M.S. *Helicon*: Surgeon G. W. Bell; H.M.S. *Penelope*: Staff-Surgeon E. Meade, Surgeon G. Smith; H.M.S. *Bittern*: Surgeon J. W. Davis; H.M.S. *Beacon*: Surgeon C. W. Hamilton.

The Medical Service for the Egyptian War.

DEPUTY SURGEON-GENERAL HANBURY has received orders to proceed to Egypt as principal medical officer of the expeditionary force. He will be assisted by Deputy Surgeon-General Ekin and Brigade Surgeon Manley, each of whom will have charge of a division. It is authoritatively stated that eight field hospitals are in course of equipment, and will be sent out as required, each being under the charge of the brigade surgeon, or a senior surgeon-major. Eighty-six medical officers have been ordered out to Egypt, in addition to those required at Malta and Cyprus.

Elections at the Paris Academie de Medecine.

At the election for a member of the Section of Medical Physics and Chemistry, to fill the vacancy left by the death of M. Briquet, the Section sent up the list of candidates as follows:—1st, *ex æquo*, MM. Gariel and Javal; 2nd, M. Bouchardet; 3rd, M. Hardy; 4th, M. Onimus. M. Gariel (who is one of the secretaries of the French Association for the Advancement of Science) was chosen by the votes of fifty-seven of the sixty-eight Academicians present.

The Cotton Districts Convalescent Fund.

A MEETING of the Governors of the Cotton Districts Convalescent Fund was held last week at the Westminster Palace Hotel, the Earl of Derby presiding. The meeting had under consideration proposals for the transfer of a plot of land adjoining the new Convalescent Home at Southport for the erection of buildings connecting the old and new hospital, in order to facilitate their joint working, and, subject to approval by the Charity Commissioners, they authorised the Building Committee to negotiate for it. Dr. Watts (the clerk) reported that of 30 beds at the Children's Sanatorium allotted to the affiliated hospital, only five and a fraction had been occupied on an average during the March quarter, and only ten and a fraction in the June quarter. As this seemed to indicate that difficulties existed in the way of candidates for treatment rather than any deficiency in the number of children seeking admission, it was resolved to effect an alteration in the rules of nomination, whereby, so long as any beds remain unoccupied, nominations may be made directly by members of the building and hospital committees.

Compulsory Notification of Infectious Diseases by Medical Men.

A FORTNIGHT since a meeting was held at Greenwich to consider the proposal to compel medical men to notify cases of infectious disease in their practice to the sanitary authorities. Many of those present spoke against the provision, whilst no one spoke in its favour.

The following resolutions were unanimously carried:—

1. That we form ourselves into an association for the simple purpose of resisting the attempts that are being made to compel medical men to notify cases of infectious disease.

2. That we affiliate with the Liverpool Association formed for a similar purpose.

A letter was directed to be sent to the Chairman of Council of the British Medical Association, requesting

him to appoint a special time at the annual meeting at Worcester for discussing this question.

Hospital Changes in Dublin.

THE appointment of Dr. Finny to the King's Professorship of Medicine in the Dublin University School of Physic involves, according to usage, his being attached, as Clinical Physician, to Sir Patrick Dun's, and no other hospital. Dr. Finny will, therefore, be obliged to resign the Physiciancy of the City of Dublin Hospital, which he has held for some years, and already several candidates for the vacancy are in the field. Amongst them is Dr. Duffey, of Mercer's Hospital, and if he should be elected the office of physician to the latter hospital will become vacant.

The pending election of Dr. McCann to the Mastership of the Rotundo Lying-in Hospital will create a second vacancy in the staff of the City of Dublin Hospital, in which institution Dr. McCann is now Gynaecologist.

Delusive Titles.

A PERSON named Greatorex, who practises without qualification in the neighbourhood of the Caledonian Road, London, is being prosecuted for having given a death certificate, falsely pretending that he is a qualified medical man. He had hoodwinked the parents of the patient by signing himself L.A.M.D., which on inquiry turned out to mean "late Army Medical Department."

Flameless Combustion.

At the recent *soirée* of the Society of Chemical Industry at Owens College, Manchester, a new theory of combustion was practically illustrated by Mr. Thomas Fletcher, of Warrington, the results being so totally unexpected that many present would, and in fact did, go away with the impression that some deception was being practised. Mr. Jacob Reese, the inventor of the Reese fusing disc, has stated his belief that if it were possible to produce combustion without flame, the temperatures and duty obtained from any fuel would be enormously increased. Mr. Fletcher now sought not only to prove the possibility of flameless combustion in more than one form, but also to demonstrate practically the enormously high temperatures which can be obtained by this means. Taking a ball of iron wire about three pounds in weight, he placed it on a slab of fire clay, and directing a blowpipe flame on it for a few seconds, he suddenly blew out the flame. The temperature increased so rapidly that in a few seconds the wrought iron fused and ran into drops, and this temperature was steadily maintained. The room was darkened, but the closest examination did not show a trace of flame, although the fact that the gas was burning was proved by repeatedly relighting and extinguishing it. The same experiment was repeated in another form by directing the flameless heat into a small fire-clay chamber, in which a refractory clay crucible, made specially for nickel melting, was partially fused and worked into a ball like soft putty, the sides of the fire clay chamber being at the same time fused. The heat was so tremendous that the blowpipe laboratory which was given up to Mr. Fletcher for the evening was much too hot to be agreeable, in spite of open windows and

ventilators. How far this discovery can be utilised remains to be seen, but it would appear that the presence of flame, usually considered to be a sign of combustion, is really an indication of imperfect results, and that the highest power is to be obtained only when flame is totally absent.

The Trade in Girls for Belgium.

THE Report of the Select Committee of the House of Lords to inquire into the state of the law relating to the protection of young girls, establishes the fact of the existence of a trade in girls between this country and Belgium for immoral purposes. The Committee also prove that juvenile immorality is alarmingly on the increase, and that cases are known of children following the profession of prostitutes from an incredibly early age. They recommend that the age of irresponsibility in girls should be raised; that persons shall be guilty of a misdemeanour who harbour girls under seventeen for immoral purposes; that girls under sixteen soliciting in the public streets shall be sent to industrial schools; and that the enforcement of the law shall be more rigorous in the case of street-walking.

The Representation of the Royal Irish University in the Medical Council.

By a short Bill, which is certain to pass, Dr. Lyons, M.P., has remedied a notable omission in the Royal Irish University Act. That Act extinguished the Queen's University, and—under it—the new University swallowed up all the functions, authorities, and privileges of the older institution, but its framers never thought of transferring the membership of the General Council with the other goods and chattels of the defunct University. Therefore, when the Queen's University ceased to exist, Dr. Banks, its Medical Council representative, found himself, so to speak, running out of lease, and without any clause for renewal. Dr. Lyons has now remedied the omission, and we assume that at the next meeting of the General Medical Council (if it ever meets this side of the legislative grave) Dr. Banks will take his seat as the representative of the more Cosmopolitan institution—the Royal Irish University.

The Unqualified Assistant System.

At Stratford Police Court last week, Mr. Henry Bowden Lyell, M.R.C.S., practising at Walthamstow, was summoned at the instance of the Medical Alliance Association, on a charge of wilfully giving a false certificate concerning the death of an army pensioner, who had died while under the care of Mr. Lyell's unqualified partner. The principal evidence given in support of the charge was that of Dr. Scoresby Jackson, a member of the Medical Alliance Association, and also registrar of births and deaths for the Walthamstow district, who produced the register containing the certificate said to be signed by the defendant. As the witness was, however, unable to swear positively that the signature was in the defendant's handwriting, the summons was dismissed.

A DENTAL EXAMINATION will be held by the Royal College of Surgeons in Ireland on Monday, the 30th of October next.

The Sunderland Conspiracy Case.

DR. ABRATH's action against the North Eastern Railway Company for the malicious prosecution of himself, together with his patient, McMann, and which extended over three days at the Durham Assizes last week, ended in a verdict for the Company. Men in their collective capacity may do, it appears, what individuals dare not. It was, however, the opinion of a high legal authority, the late Solicitor-General, Sir Hardinge Giffard, that Dr. Abrath had a good case for damages against the Company, but such is the uncertainty of law that even the highest legal authority can scarcely venture to predict the verdict of a jury in any case without finding himself in error. It does appear to be hard that any one of Her Majesty's subjects should be called upon to meet a criminal prosecution, put to a ruinous expense in establishing his innocence, and to find himself without redress of any kind.

Explosive Materials supposed to be Innocent.

MORE than a year ago a remarkable and unaccountable explosion occurred in the warehouse of a drysalter, Mr. Riley, at Castleton, near Manchester, whereby two persons lost their lives, and a third was seriously injured. It was supposed that the explosion was in some way occasioned by chlorate of potash, but how, could not be satisfactorily explained, and ultimately thought quite improbable, as salt is in itself known to be perfectly harmless and free from liability to explode, even when exposed to a considerable heat. The mysterious nature of the accident induced the Government to send an inspector of explosives to inquire into the circumstances attending it, and Captain Cundell's report has just been issued. As he could find no trace of a dangerously explosive material on the premises, he was forced to the conclusion that the explosion must have been caused by the mixture of two innocent substances which had come accidentally together on the floor of the warehouse, namely, chlorate of potash and the yellow prussiate of potash. It now turns out that these two harmless materials, when mixed together in equal proportions, do form an explosive material of a somewhat energetic nature—that they are, in fact, the chief constituents of what is known as white gunpowder.

According to the evidence of Mr. Riley and his son, a carman was delivering kegs of potash and yellow prussiate, when one of the kegs of potash slipped, and the iron hoop on the cask struck fire against the wall as it fell to the floor; that a considerable quantity of chlorate of potash and yellow prussiate was spilt upon the floor, and thus became ignited, for a considerable outburst of flame was seen to issue from the floor, and young Riley was severely burnt about the lower part of the legs. Thus, quite accidentally, a mixture of an explosive character was formed, capable of doing great mischief, but which in no way was either contemplated or brought within the scope of the Act which regulates the storage of explosive or dangerous materials.

The verdict of the jury at the time, which was that of accidental death, was perfectly correct, although it was thought that some more dangerously explosive material had been purposely brought into the warehouse with a malicious intent.

Metropolitan Hospital Sunday Fund.

THE sums collected on Hospital Sunday in June last was some two or three thousand pounds more than that of any preceding year, being upwards of £33,000. The Fund was founded in 1873, through the exertions of a few influential men interested in hospital management, who, after considerable trouble, succeeded in getting the then Lord Mayor, Sir Sidney Waterlow, to become its President, and afford it the *imprimatur* of the Mansion House. Since then the large sum of £282,000 has been collected and distributed amongst the hospitals and dispensaries of London. A separate Fund has also been established for the supply of surgical appliances. This movement has now spread from the metropolis to all parts of the country, to America, and to the Colonies, where it has become a settled institution, affording substantial aid to the work of the most useful of all charities, the hospitals.

A WHOLE family has been accidentally poisoned at Sallède, near Vic-le-Comte, in the Department of Puy-de-Dôme, by flour containing a lead-salt.

DR. COURBIN, of Bordeaux, has detected small worms in the alveoli of a dog's lung, by microscopical examination. Some were free, others were encysted. The post-mortem established pneumonia as the cause of death.

A DEATH from lightning took place at the Curragh Camp a few days since. Private Harris was struck on the left side, and his uniform from the breast down to his foot was completely torn away, one of his boots being rent in pieces. Death was instantaneous; but a comrade who was with him at the time, and was also struck by the lightning is under treatment at the hospital.

In order that due inquiry may be made—if necessary—into the position of candidates for the Fellowship of the Irish College of Surgeons, the Council of that Body have resolved—"That, unless the Council, under circumstances of urgency, shall otherwise direct, the name of each candidate for Fellowship shall be submitted to Council at least a fortnight before his application to be admitted to examination is considered."

At a meeting of the Paris Société de Chirurgie, Mr. Th. Anger recently reported a small epidemic of tetanus which came under his observation at Cochin Hospital last year. Four patients rapidly died of the disease. While demonstrator of anatomy at Clamart, the same observer witnessed the death of a sloth, together with her six young ones, from tetanus, after they had lived some time in a stable in which two horses had died of the same disease.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Norwich, Brighton, Birmingham 14; Edinburgh, Derby, Sheffield 15; Dublin, Halifax, Plymouth 16; Bristol, Cardiff 17; London, Huddersfield 18; Nottingham, Bolton, Wolverhampton, Newcastle-on-Tyne, Oldham, Birkenhead 19; Portsmouth 20; Leeds

21; Glasgow, Hull, Blackburn, Sunderland, Preston 22; Manchester, Bradford 23; Salford 24; Liverpool 25; and Leicester 26.

"MAMMARIAL BALM restores and developes the bust. Warranted sure and safe. Price one dollar. May be obtained," &c.

The *Chemist and Druggist* asks—Is it for internal or external application? Is it "to be rubbed into the roots every night"? And was it discovered on the inaccessible slopes of the Andes? What with *antis fat* and *lean*, *blooms*, *blanca*, hair producers and destroyers, dyes, bleaches; corn, wart, and pimple eradicators; and special applications for nails, hands, lips, cheeks, eyebrows, and teeth, besides such gross mechanical contrivances as nose-machines, wigs, and wooden legs, we are of opinion that if Venus herself were to "revisit the glimpses of the moon" she would be accounted a very so-so sort of party.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 34, Bombay 21, Madras 30; Paris 20; Geneva 11; Brussels 19; Amsterdam 23; Rotterdam 19, The Hague 21; Copenhagen 25; Stockholm 24; Christiania 16; St. Petersburg 49; Berlin 28; Hamburg 20; Dresden 29, Breslau 37, Vienna 25, Prague 28, Buda-Pesth, 36, Trieste 30, Rome 21, Turin 26, Venice 33, New York 28, Brooklyn 20, Philadelphia 17, and Baltimore 29. No returns have been received from Alexandria for several weeks, that city being in a state of chaos; but we fear if authentic information were obtainable the death-rate would have terribly risen during the bombardment.

THE highest death-rates per 1,000 in the large towns last week from diseases of the zymotic class were—From whooping-cough 1·3 in Sunderland and 1·2 in Birkenhead; from measles, 1·4 in Plymouth; from scarlet fever, 2·5 in Derby and 1·6 in Hull; and from fever, 0·8 in Leeds. The death rate from diarrhoea, although showing a further increase upon those which prevailed in recent weeks, was considerably below the mean rate prevailing in the corresponding week of recent years; the highest death-rates attributed to this disease last week were 7·4 in Leicester, 2·7 in Preston, 2·4 in Nottingham, and 2·3 in Salford; 8 deaths from diphtheria were returned in London, 7 in Glasgow, and 2 in Portsmouth. Small-pox caused 9 deaths in London and its suburban districts, 4 in Nottingham, one in Leeds, and one in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

PATHOLOGIST TO THE ROYAL INFIRMARY, EDINBURGH.—This post is now vacant, owing to the appointment of Dr. Hamilton to the Chair of Pathology in Aberdeen. The following is a list of the candidates:—Dr. Waller, lecturer on pathology, Minto House; Dr. Bramwell, lecturer on the practice of medicine, Park Place; Dr. Buist, lecturer on pathology, Surgeons' Hall; and Dr. Woodhead, class assistant

to the professor of pathology in the University. The appointment has always been held by an extra-mural lecturer, but attempts are being made to wrest it from the Extra-Mural School. The candidature of Dr. Woodhead is virtually that of the professor of pathology and is simply another effort to destroy the influence and usefulness of the Extra-Mural School. Already we have esoteric pathological doctrines, and it only remains for the professor to hold the appointment of pathologist to the Infirmary to complete the commercial programme which has of late been too plainly carried out by the professor of natural history. We may soon hope to see portions of diseased organs sold by the pennyworth to students.

THE SURGEONCY AND ASSISTANT-SURGEONCY TO THE EDINBURGH ROYAL INFIRMARY.—Owing to Mr. Chiene's elevation to the Chair of Surgery in the University the posts of surgeon and assistant-surgeon to the Royal Infirmary are now vacant. The former will in all probability be filled up by the appointment of Dr. Alexander Miller, lecturer on surgery in the Extra-Mural School. For the latter the following is the list of candidates:—Drs. Macgillivray, Finlay, Cotterill, and Cathcart. We may consider the individual claims of these gentlemen on some future occasion.

DEATH OF THE EX-PROFESSOR OF BOTANY IN ABERDEEN UNIVERSITY.—Dr. George Dickie, who died at Aberdeen a few days since, was a native of Aberdeen, and was educated at Marischal College. At an early age he developed strong tastes and abilities for botanical research, and he soon earned the reputation of being one of the most promising and rising botanists of his time. He held the Botanical Chair in the Queen's College, Belfast, for a number of years, and on the fusion of King's College and Marischal College into Aberdeen University he was appointed Professor of Botany. He discharged the duties for seventeen years, only resigning in 1877 on account of impaired health. Dr. Dickie had written numerous papers and published some books connected with his favourite study, the most important of which was "The Botanist's Guide," published in 1860.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 15th inst., the mortality in Edinburgh was 67, and the death-rate 15 per 1,000. Fully half of the mortality was due to diseases of the chest; 6 deaths to zymotic causes, comprising, fever 3, and scarlatina 1, the intimations being, fever 12, scarlatina 31.

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, 15th inst., was 23 per 1,000, as compared with 22 in the preceding week, 20 in the corresponding week of last year, and 22 and 18 for 1880 and 1879 respectively.

UNFOUNDED CHARGE OF RAPE AGAINST A MEDICAL MAN.—On the 17th inst., Edward Pratt Evatt, a physician and surgeon practising at Galashiels, was tried before the High Court of Justiciary, Edinburgh, on a charge of criminally assaulting a young woman who had on the 12th April last put herself in his hands for a surgical operation. After the young woman in question and Drs. Murray and Somerville had been examined, the charge was withdrawn by the Advocate's Depute, who had first consulted with Lord Adam. His Lordship then said to the jury that it would be necessary for them to return a verdict of not guilty. This the jury accordingly did, and in doing so their foreman observed that they had for a considerable time been decidedly of opinion that the verdict which His Lordship asked them to find was the only verdict which could be returned in this case. Since the charge against Dr. Evatt,

an address, signed by more than a thousand inhabitants of Galashiels, expressing the esteem in which he is held, has been presented; and when the acquittal became known, the train which contained Dr. Evatt was met at the station by the town's band, and 6,000 or 8,000 persons, who loudly cheered him. This seems to have been a most unwarrantable and unjust prosecution, and we therefore congratulate Dr. Evatt on the successful issue of the case. It is surprising that the Crown agents should have deemed it necessary to take up a case which broke down so hopelessly in the proof.

Literary Notes and Gossip.

MR. LESLIE STEPHEN, author of a "History of Modern Thought in the Eighteenth Century," has in the press a new work entitled "The Science of Ethics as Modified by the Doctrine of Evolution."

A NEW volume of the classified catalogue of the library of the Royal Institution of Great Britain, by Mr. Vincent, the Librarian, is now ready; it includes the most important works published during the last twenty-five years, placed under their respective heads, accompanied by a synopsis and indexes of authors and subjects.

FROM the half-yearly list of Messrs. J. and A. Churchill we find that thirty-eight new works, new editions, and pamphlets (of which three were American) were published by them during the past half-year. This is confirmatory of our expressed opinion of the paucity of medical authors of late, a condition which, on account of recent events, is likely to continue.

THE Council of the Society of Arts have awarded the Albert Medal of the Society for the present year to Professor Pasteur, of Paris, for "his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

THE *Sanitarian* is an American monthly magazine, devoted to the preservation of Health, Mental and Physical culture. From the number sent us, we are able to form a very favourable opinion of its contents; the article on "The Evidence of Insanity in the Brains of Criminals," by Dr. E. C. Spitzka, is well worth careful perusal. There is also an interesting article by Dr. Richard McSherry, with the curious title, "The City needs a change of air."

MR. EARDLEY BAILEY DENTON has done good service in republishing the portions of his father's lectures, "Handbook of House Sanitation," with additions by himself. The book supplies a real want, and will be of great assistance to those who wish to live in houses where the risk from disease is reduced to its minimum. The book is well printed, and fully illustrated, and it would be difficult to take exception to a work which possesses so many merits.

MR. ALFRED HAVILAND, F.R.C.S., is contributing a series of papers to *Knowledge* on "Seaside Health Resorts," which have for their object the guidance of the profession and the public in their selection of places and localities most appropriate to meet particular health requirements. Mr. Haviland's past contributions to Physical Geography and Climate eminently qualify him to speak on this important subject.

THE June number of *Science for All* contains an article by Mr. Rudler on "A Piece of Sulphur;" a very lucid résumé, by Mr. Ackroyd, of the science of "Vortex Rings;" natural history papers by Professor P. M. Duncan, on the "Ancient and Modern Animals of South America;" and on "Rock-making Rhizopods," by Mr. Herbert Carpenter. Botany is represented by a short paper on Mushrooms, by Mr. Worth.

ington Smith. On the whole the number is one of the best of the series, and is beautifully illustrated.

ALTHOUGH abjuring religious topics in these pages for very obvious reasons, we cannot allow Dr. Le Mon's assertions in the columns of *Modern Thought* to go unchallenged. In his contribution on "The Religion of France," speaking of sects and classes, he asserts that "there are also Bradlaughites," but these belong "especially to the medical profession." At home we doubt if more than a single member—we happen to have come across one—could be found professing these dangerous tenets; and putting it upon the most sordid ground, we fail to see why our confrères on the Continent should stoop to so base a creed.

MR. H. PERCIVAL has been applying some mathematical problems relative to the population of the earth. He starts with the computation that the surface of the earth comprises 52,000,000 square miles, and that the present population is 1,500,000,000. The most densely populated region is East Flanders, which has 700 inhabitants to the square mile; if every tract were as densely filled, the earth's population would, he estimates, be 36,400,000,000. He then takes the assumed increase at $\frac{1}{4}$ per cent. per annum, and concludes that we shall arrive at this consumption; i.e., 700 to the square mile, in 214.1 years, or thereabouts, allowing for war, plague, pestilence, and famine!

MR. HOLMES' "Botanical Note-Book" (Christy and Co., London) seems to us a most useful addition to the student's book-case. The glossary of terms is very handy, and supplies what has hitherto been a desideratum. The schedules for describing plants are thoroughly practical, and encourage the student to examine carefully and systematically, and one plant thus described by himself imparts more knowledge than hearing and seeing any number lectured on. This note-book should, therefore, become very popular with the members of practical botany classes, as exactly meeting their requirements. The two last charts are very important, as they lay clearly before the eye the diagnostics of similar natural orders, and likewise explain what plants can be obtained at the various seasons.

FOLLOWING up the plan referred to in our last column of "Literary Notes and Gossip," the Great Eastern Railway Company have issued a second of their series of Holiday Handbooks, under the editorship of Mr. Percy Lindley. These little books are pleasantly and instructively written, and will be much appreciated by those in search of a new route at a moderate cost for their summer tour. No. II. is entitled "Holidays in Holland," and comprises all the necessary railway, hotel, and travelling information, with descriptive and illustrated text, at the modest cost of one penny. The last number of this journal contained a correspondent's description of a holiday thus taken, and his example will probably be emulated by a good many of our readers. These guides are obtainable at the leading booksellers and railway bookstalls throughout the Kingdom.

AT the recent annual meeting of the Royal Society of Edinburgh, the medals were awarded to the distinguished essayists, and the President explained that the grounds on which the Keith prize had been awarded, apart from the purely scientific point of view, from which it had very great merit indeed, was the practical nature of Professor Chrystal's essay. With reference to the Neill prize, he said that the theory which Mr. Murray had put forward as to the structure and origin of coral reefs and islands rendered it unnecessary to the geologist to assume, in explanation of some of the more difficult problems presented to him by his science, the occurrence of great and repeated general subsidences, which were found to form one of the great difficulties of geology; and that, from the general acceptance that the theory was receiving from scientific men, particularly from those specialists whose domains in science it touched most nearly, it was already taking the place of the theory so long held by Professor Darwin.

COMMENTING on the recent award of the Boylston prize to Mr. T. M. Dolan, of Halifax, Yorkshire, the *Boston Medical Journal* remarks:—"This is the third successive occasion on which the prize has been awarded to a competitor outside of the United States. It is a cause for congratulation that

America can offer prizes sufficiently liberal for international competition. It was pleasing rather than otherwise when the first award to an Englishman showed that the competition was not limited to inhabitants of a single country; that that award should be immediately followed by two others of like nature is far from flattering. We trust it is a nobler motive than selfishness that causes us to hope that the next announcement may be more in accord with national pride." Quite so! and perhaps if our contemporary would follow up its excellent advice by counselling our American cousins to cease indulging in their proclivities for piracy of English and Continental authors' works, they would have more leisure to think over and to write essays, the prizes for which now find their way this side of the water.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, June 14th:—Manual for the Physiological Laboratory, by Vincent Harris, M.D., and D'Arcy Power, M.A. Oxon. (2nd edition). Spasmodic Asthma, by W. E. Stevenson, M.B. (2nd edition). On Failure of Brain Power, by Julius Althaus, M.D. (2nd edition). Mineral Waters: their Use and Applications, by J. Milner Fothergill, M.D. Outlines of the Science and Practice of Medicine, by W. Aitken, M.D., F.R.S. (2nd edition). Physiology and Pathology of the Blood, by R. Norris, M.D. The Medical Digest, by Richard Neale, M.D. (2nd edition). Student's Guide to Diseases of the Eye, by E. Nettleship, F.R.C.S. (2nd edition). The Medical Man's Handy-book, by W. Shepperson. L'Année Médicale for 1881, par le Dr. Bournville. Clinical Lectures on Diseases of the Nervous System, by Thos. Buzzard, M.D. Experimental Physiology: its Benefits to Mankind, by R. Owen, M.D., F.R.S. The Retrospect of Medicine, Vol. LXXXV., edited by Drs. W. and J. Braithwaite. Eastbourne as a Summer Residence and Winter Resort, by G. Moseley, F.R.C.S.

Obituary.

DR. ANDREW BUCHANAN, OF GLASGOW.

IN the ranks of the medical profession in Glasgow a link has been severed which connects it with a past generation of medical practitioners, and one has been removed who for the long period of 60 years has done much by his genius to advance its reputation, and by his character to maintain the dignity of which it justly boasts.

Andrew Buchanan, M.D., LL.D. (*clarum et venerabile nomen*), died at Craigmore, Birnam, near Dunkeld, on the 9th day of July, having attained the patriarchal age of eighty-three, with intellect of pristine vigour. Dr. Buchanan was essentially a Glasgow man, and was the worthy inheritor of the name of a worthy and honourable Glasgow family. His father was a well-known merchant in the city in the olden times, who, ere the palatial residences of the West End were ever dreamt of, in the times of the "Virginia Lords," with his family resided in Saint Andrew's Square, in immediate proximity to The Green. Dr. Buchanan received his early education at the High School of Glasgow—the educational nursery of so many men of distinction. His brother Walter, who still survives him, and who worthily represented his native city in Parliament, attended this school simultaneously with him, and he delighted quite recently to recall the boyish freaks and adventures of the golden season of virtuous youth. Leaving school, he studied at the University of his native city, enjoying the benefits of a full Arts curriculum, which laid the foundation of the excellence of his subsequent contributions to medical literature. After the usual course of medical study he graduated M.D. in 1822, and took the Fellowship of the Faculty of Physicians and Surgeons in 1827. As was then the custom, and before everything medical had become Germanised, Dr. Buchanan passed a considerable period of his time in Paris, and prior to returning to his native city extended his peregrinations to Italy, to whose charms his education and culture rendered him eminently susceptible.

In early life Dr. Andrew Buchanan was what was then called "a Radical," but the tide of public opinion having gradually advanced, he was left on the sea of politics a pronounced Whig. Conformably with his political opinions,

so were his professional ones, and he did not disdain, contrary to what now obtains, to climb the steep to fame and honour at its lowest. He felt that no professional position could dishonour any man; rather it was his to do honour to the position. Consequently he early sought and obtained a parochial appointment, rather with a view to obtaining practical experience than of leading to practice. In this capacity he came in contact with the great epidemic of cholera in 1832, and his experiences and those of his *compères*, to whom he did ample justice—notably to the late Professor Lawrie—were no less thrilling in narrative than they were honourable to the brave men, who, taking their lives in their hands, sought the alleviation of human suffering, and the general good of mankind.

In 1828 the first volume of the *Glasgow Medical Journal* appeared, and Dr. Buchanan was one of its original founders. It was then only a quarterly journal. Perhaps a return to the good old practice might still be beneficial to medical literature. The first volume was edited by William Mackenzie, who became the celebrated oculist. The first number contains three papers by Dr. Buchanan. Volume IV. was edited by Dr. Buchanan, in conjunction with the late Dr. William Weir. Only five yearly numbers of this instalment of the *Glasgow Medical Journal* appeared. To all of them Dr. Buchanan largely contributed, and the five numbers, from 1828 to 1832, are extremely creditable to the profession in Glasgow in those early days. Comparatively early in life Dr. Buchanan became connected with the surgical department of the Royal Infirmary, a position which he resigned on attaining the age of sixty, in obedience to the then rules. He lectured on Forensic Medicine at Anderson's College, then, however, and long afterwards termed "the Andersonian." From this school, in common with so many other of its lecturers, he was transferred to the University. This was on the occasion of the founding of the Chair of the Institutes of Medicine. It is not necessary here to refer to the changes which then took place further than to relate that between Drs. Harry Rainy and Buchanan the courtesy of gentlemen and the good feeling of professional brethren remained unruffled. For over thirty-five years Dr. Buchanan, by the ingenuity of his experiments, and the erudition of his prelections, did much to lay a sound and rational foundation of practical medicine. His lectures were constructed on the model, as he told the writer, of the famous *Gregory's Conspiculus*.

As an operator Dr. Buchanan was cautious, aiming at no show, preferring rather that the necessity for operation, and the nature of it, were based on sound induction and pressing necessity. Like many other surgeons, he was tender-hearted to a degree which his manner failed to convey or discover. With his own operation for lithotomy—viz., that by the rectangular staff, it is to be desired that his name will be long associated. It is still a favourite operation in Glasgow, and in the brilliant hands of Dr. Eben. Watson has afforded a marvellously gratifying result. He was the originator of a new operation for the restoration of the lip, after the removal of the parts, especially by cancer; and he was wont to complain with just reason that while his was the honour, another sought the credit. He was the first to discover that in combination with starch, large doses of iodine could be beneficially introduced into the system. His observations on this subject have since been confirmed, and are now accepted by the profession.

Of his frequent contributions to literature, the limits of our space forbid our saying much. They always revealed an ingenious, logical, and mathematical mind. In 1834 he published a well-expressed and convincing paper on the evils arising from "Monopolies in Learning." He lived to see the day when legislation to remove many of these evils is imminent.

The closing sentences of this paper, in view of existing conditions, may be regarded as almost prophetic:—

"All the Scotch Universities possessed originally a constitution which rendered them well adapted to promote the objects for which they were instituted—the advancement and the diffusion of learning. But abuses have gradually crept into them, and they are now far less efficient than they might be in diffusing learning; while to all advancement of it they are absolute hindrances. To endeavour to procure a reformation of these abuses, I consider to be the duty of every man who is himself educated, or takes any interest in the education of others; and as we are now blessed with

a Government that has already so often listened to the voice of the public rather than to the whisperings of interested individuals, I entertain no doubt that a judicious representation to Parliament of the present state of education throughout Scotland would be soon followed by the abolition of those monopolies the nature and effect of which it has been my object to illustrate."

His paper on "The Forces which carry on the Circulation of the Blood" attracted the attention of the highest physiological experts. Another, entitled "Why is the Right Hand Stronger than the Left?" is an admirable piece of subtle reasoning. Dr. Buchanan likewise made some important observations on the manner in which serous fluids are exuded from the body, and how they become affected by the various constituents of the blood when added to them. He published on the subject, and a professor of the University of Aberdeen recently referred to these papers as classical.

Till his dying day he had pen in hand. Among his most recent contributions is a discussion with Mr. Taylor, M.P., in our columns, "On the Protective Influences of Vaccination," in which he was an unshaken believer. Dr. Buchanan was an excellent Latin scholar; and it is no disgrace to the profession in Glasgow to say that even at the time of his death we doubt if it contained a single member who could write the preface in this elegant language which he wrote for his new edition of George Buchanan's *Psalms*, which we believe is now ready for the press, if not nearing completion. Only one well grounded in the language could make the delicate corrections in punctuation and text which Dr. Buchanan did; and his remarkable freshness and profound knowledge of the Latin, considering his age, must be regarded as quite unusual. Of Professor Buchanan in private life it is somewhat difficult for a friend and pupil to speak. An affectionate father, his soul was rent by the loss, from typhus fever, within twenty years ago, of a promising and amiable son. Only those who knew him intimately could appreciate the depth and poignancy of his wound. He is survived by a daughter, several grand children, and an estimable and accomplished wife, for whom much and genuine sympathy is felt.

In matters relating to professional honour, Dr. Buchanan had all the punctiliousness of a high-born gentleman. "Live well and honourably, that you may enjoy a happy old age," was quite a recent observation of his. He possessed a keen sense of humour, and few delighted more in an apt Latin epigram. His contests in this manner with his accomplished friend Professor Nichol belong, we fear, to an age well-nigh extinct. Andrew Buchanan had the courage of his opinions, and warmly sympathised with that courage in others, no matter how it might oppress. "My mind to me a kingdom is," was an aphorism he never disputed. He has passed away, ripe in years, equally ripe in honour, and in the affection of his numerous pupils throughout the world, and of the respectable *clientèle* who put well-merited confidence in one who was emphatically a "good physician."

*Ille quidem plenus annis ablit, plenus honoribus,
Illis etiam quos recusavit.*

Correspondence.

THE ETHICS OF COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I regret that I have again to trespass upon your valuable space; but a letter appeared in your impression of the 12th inst. which demands some reply from me.

Mr. Sidney Davies, B.A. (Oxon.), M.R.C.S., therein undertakes to deny that "the infringement of the rights of others is the only limit to be placed upon the rights of each," as I had maintained in reference to compulsory vaccination. He is welcome to his opinion, which, nevertheless, conflicts with that of not less eminent moralists, for instance, Mr. Herbert Spencer. Mr. Davies cites the law in reference to gamblers and drunkards in support of his views, but, unfortunately, the law as it exists is no criterion of the law as it should be. The objection concerning suicides is more plausible, and I expected that it would be raised; I reply that suicides are either sane or insane: if the latter they do not come under the law of equal liberties; if the former (if such there be) I should deem their own opinion upon the subject superior to that of others. Mr. Davies observes, "if vaccination were not compulsory the (unvaccinated) minority would probably be much larger and

might even become a majority." Could a more suicidal statement be made? To think that after 80 years of vaccination it has proved itself of so little value that the majority would reject it if not whipped up by the vaccination officer! To make any practice compulsory is to take away the natural healthy stimulus to its adoption which the result of the neglect of it would occasion. And to erect State endowments around any medical rite is to create vested interests in that rite which will stultify all progressive reform from without.

Mr. Davies misquotes when he accuses me of saying that "the Public Health Act is a sufficient protection against anyone who suffers from small-pox communicating the disease to another." But if we may judge from the case of Leicester, notoriously the worst-vaccinated town in England, and where there have been but 3 deaths from small-pox since 1872, and where all recent outbreaks have been completely stamped out by isolation of the affected, it would seem that there are other methods of dealing effectually with small-pox epidemics than the cumulative penalties and imprisonment inflicted under the Compulsory Vaccination Acts.

Yours, &c.,

W. J. COLLINS, M.B., B.S., B.Sc., Lond.

1 Albert Terrace, Regent's Park, N.W.,
July 20th, 1882.

Royal College of Surgeons of England.—The following candidates having passed the required examination for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on Monday, July 17th:—

Herbert Harding Ashdown, M.B. Edin., Edinburgh; Joseph Shepherd Bolton, M.B. Edin., Finsstock, Oxon.; Joseph Collier, L.S.A., Manchester; William Henry Dobie, M.B. Edin., Chester; Ernest Augustus Hyrons, L.R.C.P. Edin., Padmore; Granville Jameson, M.B. Edin., Heywood, Manchester; Arthur Corrie Keop, M.B. Edin., Wollaston; Bernard Langley Miles, M.B. Edin., Edinburgh; John Brady Nash, M.B. Edin., New South Wales; Ernest Frederick Neve, M.B. Edin., Hurstpierpoint; Malcolm Alex. Nicholson, M.B. Toronto, East Dulwich; Chas. Joseph Parkinson, L.S.A., Greenheys, Manchester; George de Joncourt Patterson, M.B. Dub., Dublin; William Elliott Price, M.B. Durh., Hereford; Silva Prasad Roy, M.B. Calcutta, Calcutta; Narendra Prasanna Sinha, L.M. Bengal, Calcutta; Joseph John Stapleton, M.B. Edin., New South Wales.

The following were admitted on Tuesday, July 18th:—

Charles Montague Chadwick, L.S.A., Tunbridge Wells; Harold Hendley, Hammersmith; William Heaton Horrocks, Bolton, Lancashire; Sanford Seobell Lessey, Ealing; Bowen Stilon Menda, Blackheath; H. M. Nelson Milton, L.S.A., Clapham; James Montford, L.R.C.P. Edin., Church Stoke; Frank Ernest Mugrave, Leeds; John Howard North, Walsall; Alfred Temple Perkins, L.R.C.P. Edin., Stoke Newington; George Preston, Barton, near Manchester; John Dudley Price, Dudley; Walter Seachard, Boston Spa; John Walday, Dartington; William Canas Wilkinson, Sydney, New South Wales; Arthur Henry Wilson, Ilington Square, Liverpool; John Sheldon Withers, Sale, Cheshire.

The following were admitted on Wednesday, July 19th:—

William Edward Andland, Milnthorpe; Cedric Challinor, Bolton; F. J. Fitzgerald Culhane, Hastings; Edward Alfred Dingley, Sherborne, Dorset; J. J. Conway Donnet, Dover; Hedley Vicars Drew, Gloucester Place; David John Swansa; David Llewellyn Jones, Llandilo, South Wales; Thomas Pagan Lowe, Burton-on-Trent; Charles Arthur Morris, Lower Norwood; John Evans Penn, Plymouth.

Royal University of Ireland.—The following candidates having satisfied the Examiners at the recent Courts, received the degrees of the University:—

Doctor in Medicine.—Percy Allport, Martin Henry Atcock, Thomas Cahill, William Courtney, Timothy Joseph Crowley, Piers Joseph Daly, Luke Gerald Dillon, Patrick Joseph G. Ivey, John C. Hackett, William Edward Hadden, Henry Aylmer Haines, Samuel Hamill, Samuel Hamilton, Chas. James Holmes, James Macgregor Lithgow, Connor Joseph O'Loughlin Maguire, Robert Carmichael Moor, Patrick O'Gorman, Thomas H. O'Shaughnessy, John Mortlock Phillips, Leonard Robinson, George Atkins Rountree, Arthur W. Sandford, James M. F. Shine, Samuel Stronze, John Wilgar Taylor, Joseph H. Whelan, John W. Williams, James Vance Young.

Master of Surgery.—Percy Allport, Thomas Cahill, Wm. Courtney, Timothy J. Crowley, Chas. Daly, Piers Joseph Daly, Luke Gerald Dillon, John C. Hackett, William Edw. Hadden, Samuel Hamilton, Chas. J. Holmes, Samuel William Johnson, William Kelly, Daniel Leane, Edward M'Connell, John J. M'Curick, Connor Joseph O'Loughlin Maguire, Robert Carmichael Moore, Tho. H. O'Shaughnessy, Ferdinand A. Parcell, Leonard Robinson, Robert Leonard Rutherford, Arthur W. Sandford, Jas. M. F. Shine, Samuel Stronze, John Wilgar Taylor, Joseph H. Whelan, John W. Williams, Charles Wiseman.

Diploma in Midwifery.—Percy Allport, Thomas Cahill, James Craik, Timothy J. Crowley, Piers J. Daly, Patrick J. Galtway, John C. Hackett, William Edw. Hadden, Chas. J. Holmes, William Nelson, Arthur W. Sandford, Jas. M. F. Shine, Joseph H. Whelan, Charles Wiseman.

King and Queen's College of Physicians in Ireland.—The following candidates having passed the necessary exami-

nations during the present month, received the diplomas of this College:—

For the Licences to practise Medicine and Midwifery.—Sydenham Davis Chandlee, Austin Nathaniel Cooper, John Crammin, Owen Henry Evans, Alexander Fleming Harper, Robert John Heatly, John James Irvine, John Henry O'Dowd McGuinness, John McMillan, John Robert Mallins, Katherine Mitchell, Julia Caroline Mitchell-Swaagman, Robert James Tate, William Henry Stoney Walker, David Williams Whitfield, Michael Thomas Yarr.

For the Licence to practise Medicine only.—Alfred Benjamin Baka, Walter Boyd, Matthew O'Reilly.

For the Licence to practise Midwifery only.—Edmond MacWilliam Bourke, Alfred Adolphus Hayes, William Keith Scroggie, Richard Campbell, M.D. Q.U.I.

The following Licentiate in Medicine of the College, having complied with the by-laws relating to Membership, pursuant to the provisions of the Supplemental Charter of 1878, has been duly enrolled a Member of the College:—

Richard Francis Tobin, Licentiate 1874, Surgeon-Major A.M.D.

Society for Relief of Widows and Orphans of Medical Men.—At the last quarterly Court of Directors of the above Society, Sir George Burrows, Bt., the President, in the chair, a sum of £1,291 10s. was voted to be distributed among 62 widows, 7 orphans, and 3 orphans on the Copeland Fund. The expenses of the quarter were £44 7s. 6d. Seven new members were elected, the deaths of 4 reported, and 2 had ceased to be members. Fresh applications were read from 3 widows and 1 orphan, and the death of one orphan in receipt of grants since 1877 was reported. The consideration of the proposed alteration of the by-laws was postponed till the October Court.

Catholic University Medical School.—The following prizes were awarded at the termination of the summer session:—Practical Chemistry: John Buggy, F. W. McCauley. Materia Medica: Frederick Mandel. Medical Jurisprudence: Peter O'Connell, Alexander Stewart. Botany: Daniel McDonnell (first); Bernard Forde and John J. Tobin (equal). University Exhibition (£20) in Practical Chemistry, Materia Medica, and Medical Jurisprudence combined: Francis W. McCauley.

Notices to Correspondents.

Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 25 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MR. PARKER (Bath).—Your letter is so confused that we are unable to arrive at a conclusion as to its exact purport. You seem to have mixed up the treatment of lunatics, the education of the deaf and dumb, and the diet of all classes, without evolving or suggesting a definite idea in connection with either.

MR. PARSONS (Southwark).—Considerable diversity of opinion exists on the point, even among those who have made the subject their especial study. Our inclination is towards the view propounded in your letter, and we do not think it will be considered absurd or extravagant if embodied in your intended paper.

FEES FOR ATTENDANCE ON REQUISITION OF THE POLICE.—"Surgeon" says: I was called on by the Constabulary to attend a serious case some miles from my residence in the country. At the time neither the constable who demanded my attendance or I knew whether the case would require continued attendance or not. As it subsequently turned out (the case being one showing symptoms of compression of brain as result of injury inflicted by a heavy instrument), the case did require continued attendance, and I attended for upwards of three weeks, until I deemed it advisable to have the injured man removed to hospital. On sending in my bill the Constabulary refused payment for more than one visit, saying that they sent the medical officer of the district to attend the injured party, and that my attendance was voluntary. I had no means of ascertaining that another medical man was in attendance, as my treatment was carried out throughout, and the facts of the case show clearly that he could not, even if he were willing, treat the case until my services were suspended. Am I to leave a case of a man whose life is in danger until I am assured that he is provided with other medical attendance? and if not, am I not bound to attend and to recover legally for such attendance from those who first demanded my services?

[The Constabulary employed our correspondent, and, if they did not distinctly specify that it was for a single visit, we believe that their contract was for all attendance to treat and cure the case. Their

liability would be quite clear if it were shown that they knew of the continuous attendance and did not warn the doctor that they repudiated responsibility. Their calling in one or fifty other practitioners would not in the least relieve them from liability.—Ed.]

INTERFERENCE WITH ANOTHER PRACTITIONER'S PATIENTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I am anxious to know your opinion about the medical etiquette shown by a neighbouring practitioner. He occasionally pays visits, "friendly, or otherwise," to a family residing in this village, and on his last visit, which was to-day, he went, accompanied by his host, to see a pauper patient of mine, on whom he must have known I was in attendance.

The words of the patient to me were thus, a few minutes after his departure—viz., that "if he did not go into the union workhouse he would be dead very shortly."

I should like to know the means adopted to prevent such unprofessional practice, as it has not been the first on myself and others.

Yours faithfully,

JOSEPH MACNAMARA, L.R.C.S.I., &c.

Urrlingford, co. Kilkenny,
July 8th, 1882.

[Such conduct is at variance not only with medical etiquette, but with common professional decency. There is, however, no way of making a gentleman out of a person whose sense of propriety is uneducated. We should advise a firm, but dignified, remonstrance, and possibly, if this be unavailing, an appeal to the Irish Medical Association.—Ed.]

MYOSOTIS.—Your query shall be answered in our next.

RED TICKETS.—"Atlas" asks: Is it legal for a member of a dispensary committee to issue a visiting ticket without an application from the patient or his friends, and even without their knowledge, on merely hearing of the illness? Having visited the person and ascertained these facts, can I sue the committee member for my fee for such a proceeding?

[1. The issue of a ticket without request is contrary to the obvious intention of the Medical Charities Act, which, in all its clauses, speaks of the issue of a ticket to "the applicant." But sec. 9 of the Act ("Irish Medical Directory," page 513), which decides the matter, leaves to a committee-man or warden full power to issue the ticket when he thinks fit; nor do the dispensary regulations in any way restrict that power. A case might arise in which the patient was insensible, and therefore unable to ask for a ticket. 2. No, unless the ticket has been issued to an improper person, or be not filled up according to rule.—Ed.]

DR. J. HALLIDAY CROOK (Edinburgh).—Your interesting paper on "Atresia Vaginalis" to hand is marked for early insertion.

MR. A. PHILLIPS HILLS (Battersea) is thanked for the report of the meeting, but as it would have no special interest to our readers, we are unable to afford it space. We nevertheless think that if the said report be a correct one of the proceedings, the gentleman referred to was very badly treated, and we rejoice at the confusion of "the conspirators."

DREAMS OF A DISTRACTED CURATOR.

(ON THE EVE OF THE 17TH JULY, 1882.)

THE following poetical effusion on the recent election to the Chair of Surgery in the University of Edinburgh has been sent us by a correspondent:—

There are four corners to my bed,
There are four Surgeons round my head:
Duncan, Chiene, Bell, and Watson,
All are dancing with their hats on;
Watson, Duncan, Bell, and Chiene
Amble with fantastic mien;
Chiene and Watson, Bell and Duncan
Play at leap-frog without funkin';
Duncan, Watson, Chiene, and Bell
Execute a dance of hell.
Faster, faster, faster, faster,
Till my weary brain they master.
Then each shouts, "You can't refuse;
"Choose me, choose me, choose me, choose."
"Oh!" I groan, "You're each so good,
"I can't refuse ye if I would."
"So now your frantic movements spare,
"And each one kindly take a chair."
"Yah!" they cry, "You're making fun;
"Each take a Chair! there's only one!"
I start. The rabble rout has fled,
And I sit wakeful on my bed;
But find beneath the morning beam
The Surgeons still are not a dream.

RHADAMANTHUS.

DR. F. J. T. (Brussels).—Thanks for your offer; but as our department for translations is now fully provided for, we are at present unable to accept it. We will, however, keep your letter in mind.

W. T. W.—The gentleman referred to died about three years since; one of his children is now in the Royal Medical Benevolent College, and the rest, we believe, are fairly well provided for. We do not know the present address of the widow.

ONE TRED.—Doubtless you have found it up-hill work; but we do not see you have cause to despair; in one or other of our rising Colonies you would find ample occupation, and you possibly could "work out" your passage free of cost by arrangement with one of the shipping companies.

DR. T. KING CHAMBERS.—The writer is at present absent from England, but will return in a few days, when your inquiries will be answered.

A. G. L.—The operation has been revived of late years to some extent. It was performed successfully on a negro boy two years ago, and recently on several occasions in this country.

Vacancies.

Bathdrum Union, Aughrim Dispensary.—Medical Officer. Salary, £120, and the usual fees for vaccination. Election, July 29th.

Royal Isle of Wight Infirmary, Ryde.—House Surgeon and Secretary. Salary, £50, with board, &c. Applications to be sent to the Secretary before August 8th.

Ardwick and Ancoats Dispensary and Ancoats Hospital.—Resident Junior House Surgeon. Salary, £100 per annum, advancing to £120 second year. Furnished rooms and attendance provided free. Applications and testimonials to be addressed, up to August 1st, to the Hon. Secretary.

The General Hospital, Birmingham.—Resident Medical Officer and Resident Surgical Officer. The salary of each will be £130 per annum, with board and residence. Applications to be sent to the House Governor, on or before July 31st.

Appointments.

COOPER, G. F., M.R.C.S., L.R.C.P., Resident Accoucheur to St. Thomas's Hospital, London.

DANCY, H. M., M.D. Glas., Medical Officer to the Farnsfield District of the Southwell Union.

DUNCAN, W. A., M.D., L.R.C.S., M.R.C.S., House Surgeon to St. Thomas's Hospital, London.

FELL, W., M.A., M.B. Oxon., L.R.C.P., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital, London.

HAG BROWN, C. W., M.R.C.S., House Surgeon to Thomas's Hospital, London.

JONES, W., M.A., M.B. Oxon., B.Sc. Lond., House Physician to St. Thomas's Hospital, London.

MARSDEN, T., M.R.C.S., Medical Officer to the Third District and Workhouse, Bridgewater Union.

MILTON, H. M., M.R.C.S., Assistant House Physician to St. Thomas's Hospital, London.

MORTON, C. A., M.R.C.S., L.R.C.P. Lond., Senior House Surgeon to the Stanley Hospital, Liverpool.

RUSSELL, M. W. H., M.R.C.S., Resident Medical Officer to the Bath Royal United Hospital.

SANDERS, John William, M.D., Resident Medical Officer to the Bethnal Green Infirmary.

SHAW, W., M.R.C.S., Medical Officer to the Burghill District, Hereford Union.

WELLS, A. E., L.R.C.P., M.R.C.S., House Physician to St. Thomas's Hospital, London.

WHITE, E. A., M.D. C.M. Aber., Medical Officer to the Third District of the Malmesbury Union.

WHITE, E. F., M.R.C.S., House Physician to St. Thomas's Hospital, London.

WILSON, C. W., M.B. Durh., M.R.C.S., Medical Officer to the Southern District and Workhouse of the Cirencester Union.

WOODHEAD, G. S., M.D. C.M., M.R.C.P. Ed., Pathologist to the Royal Hospital for Sick Children, Edinburgh.

Births.

BROWN.—July 21st, at Coombe Lodge, Peckham, the wife of J. Alexander Brown, M.R.C.S., of a son.

FRAZER.—July 14th, at The Seven Houses, Armagh, the wife of Henry Frazer, M.D., of a son.

GOODHART.—July 24th, at Blackheath, the wife of J. F. Goodhart, M.D., F.R.C.P., of Weymouth Street, London, of a son.

O'FLAHERTY.—July 16th, at 18 Tivoli Terrace, North, Kingstown, the wife of Richard G. O'Flaherty, M.B., of a daughter.

Marriages.

BAILEY—BALDWIN.—July 19th, at Dublin, Hunt Johnson Bailey, M.D., late Surgeon Army Medical Department, to Emma, daughter of Thomas Baldwin, Esq.

BRODERICK—CROCKFORD.—July 20th, at the Parish Church, Passmarsh, Sussex, C. G. Broderick, L.R.C.P. Ed., to Julia, daughter of Henry Crockford, Esq., of Flackley Ash.

Deaths.

ATKINSON.—July 18th, at Broadstairs, J. C. Atkinson, F.R.C.P., aged 32, son of Dr. J. C. Atkinson, of Kew Green.

BARTLEY.—July 21st, at his residence, Weston-super-Mare, R. T. Bartley, M.D., late of Clifton, aged 62.

DICKIE.—July 16th, at Albion Terrace, Aberdeen, George Dickie, M.D., F.R.S., Emeritus Professor of Botany.

HARVEY.—July 16th, at St. Mark's Terrace, Lincoln, Richard Sutton Harvey, J.P., & F.R.C.S., aged 79.

LANGAN.—July 18th, at Longford, Francis Langan, M.D., aged 32.

MILNER.—July 11th, at The Crescent, Salford, Ralph Milner, M.R.C.S., aged 64.

MOFFAT.—July 16th, Thomas Barbour Moffat, M.D., of Hawarden, Flintshire, aged 69.

SILVER.—July 16th, at Upper Tooting, Alexander Silver, M.A., M.D., M.R.C.P., Physician to Charing Cross Hospital, aged 41.

WAKEFIELD.—July 23rd, at Hereford, Gilbert Wakefield, M.R.C.S., of Canonbury, aged 89.

WILSON.—July 17th, Stewart Wilson, M.D., second son of late Daniel Wilson, Esq., Omagh.

A Course of Lectures

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE IV.—(Concluded).

THE greater the degree of hereditary proclivity the less the need for the exciting cause. We may note also that we often frequently have to witness in the case of scrofula the influence of what may be called contributory causes, such for instance as the occurrence of an exanthem or other acute illness. We have then to examine as to what may be the influence under which a proclivity to inflammation of the scrofulous type may arise, and we shall probably be not much mistaken if we make answer as we should do in the case of rickets that they are largely due to deficient and unsuitable food; but that, at the same time, it must be admitted that climate, clothing, and weather take each a very considerable share. As regards diet, it is probably a deficiency of fatty matters, such as butter, oil, and the other various forms of animal and vegetable fat, which is influential; and as regards climate, deficiency of sun and exposure to damp and cold. Scrofula as we see it is probably always inherited, but it is often probably largely increased by exposure to the causes hinted at. Possibly there are few practicable dietetic changes which would be more beneficial to our English population, in reference to scrofula, than a large increase in the consumption of butter and other animal fats. The comparative immunity of those who use the fish oils as articles of food, and the prophylactic virtues of

cod-liver oil amongst ourselves are, I believe, established facts, and their lesson is of considerable importance in reference to the dietetic causes of scrofula. We are enabled at the present time to speak much more definitely as to the diseases which should be classed as scrofulous, and as to their essential connection with the tendency to tuberculosis than we were some years ago. A considerable number of diseases of the skin, of the bones, of the eye, have been conclusively removed from the scrofulous group, and placed under their proper designations, as cryptogamic in the one case, and syphilitic in the other. So far has this gone that I can easily imagine that there may be some who think that I have given too wide a definition of scrofula, when I asserted that it is not always associated with the growth of crude tubercle. To such critics I will produce the instance of scrofulous ophthalmia, which usually consists of a chronic, slow-to-heal, ulceration of the cornea, unquestionably dependent upon a constitutional cause, and often coincident with other scrofulous manifestations. There are also diseases I cannot but believe, amongst the inflammations of joints which are slow, comparatively painless in the ordinary sense of the word scrofulous, and occurring in the relatives of those who are themselves tuberculous, but in which yet it is impossible to prove the presence of tubercle either in bone or synovial membrane. The frequent and comparatively easy, and often permanent cure of many forms of scrofulous inflammation is also, I think, another reason for believing that, although tubercle is its ordinary goal, it is by no means always reached. The scrofulous diathesis is indeed very ill-defined, and, in many instances, shades off very gradually into other states of defective organisation. How closely, for instance, are many conditions which are called scrofulous associated with those peculiar states of feeble circulation and irritable tissues which give liability to chilblains, swollen lips, and the like affections? Yet these latter are not probably in any strong degree indicative of tendency to tuberculosis. The liability to rickets, in other words to a derangement of health in infancy, of which defective ossification is the chief, but by no means the only result, should unquestionably rank as a diathesis. It is one, however, which is usually,

though not quite invariably terminable at a certain period of life. In very rare instances, so rare as to be almost doubtful, it may begin during intra-uterine life, but usually its advent is delayed until near the end of lactation, and it reaches its climax and begins to subside just at the time when the child, hitherto carefully restricted to very few articles of food, and mainly to milk, is allowed to indulge its tastes, and to have variety. With such facts the first suspicion must certainly be that it is probably dependent on a milk regimen, and in the main no doubt this suspicion is correct. In numberless instances it has been proved that the milk upon which children have become "rickety" was distinctly poor in quality. The advantages in change of regimen are almost always well-marked, and although some experimenters on the lower animals have failed in the artificial production of rickets, through restricted food others appear to have succeeded. Whilst, however, we may safely believe that defects in diet are the main cause of rickets, and that they may be effectual in the almost entire absence of others, yet it is probable that others are usually present and contributory. In the discussion on rickets which took place at the Pathological Society two years ago several speakers drew attention to the fact that the disease is very rare in sunny climates, although infantile inanition from poor food may be common. Mr. Spencer Watson in particular used arguments which made it very probable that free exposure to sunlight and warmth would do much to enable a child improperly fed to yet effect assimilation in such a way as to keep clear of rickets. We may certainly believe it probable that our climate and the narrow sunless streets of our large towns take their share in the production of what was once known on the Continent as "the English disease." Let me say one word here to repudiate the suggestion which has recently come from Paris, that inherited syphilis is the real cause of rickets. The two diatheses are probably quite distinct, although they may often co-exist, and in other instances may simulate each other. Inherited syphilis, as the labours of Taylor in New York, M. Parrot in Paris, and Drs. Barlow and Lees amongst ourselves have shown us, may frequently produce swelling about the epiphyses, and a state of general tenderness of the skull due to osteitis which might be mistaken for rickets.

A word or two must here be said respecting a disease of the osseous system of great variety which has been named rickets of the adult. I allude to osteo-malacia, or fragilitas ossium. It is probable that maladies having relation to different causes have been confused together under this title. But respecting a certain number of the best-marked cases, there appears good reason to believe that the disease is really a form of rickets, and that the differences observed between the two maladies are chiefly due to the very different condition of the osseous system as regards its development at the time of attack. Trousseau has recorded a case in which osteo-malacia attacked a woman of 70 who had been rickety in childhood, and another case in which this disease was cured rapidly by the use of cod-liver oil and liberal diet. There is a skeleton in the Brighton Museum which was obtained through the zeal of the accomplished physician the late Dr. Ormerod, which is one of the best examples of osteo-malacia which I have ever seen. The man had had innumerable fractures, and partly through thin molimen and partly through bending of his bones had lost more than two feet of his stature. In this instance the man's children were much deformed by infantile rickets. Although as an ordinary thing the diathesis of rickets, if not fatal, passes away as age advances, and under the influence of judicious dietetic treatment, we may reasonably suspect that there are a few cases in which it does not do so, and that it is quite possible for it to be reproduced or even initiated in adult life. In respect to its rapid subsidence, and usually its complete disappearance when the diet is improved, the rachitic diathesis has a close parallel in scurvy. The latter malady is indeed of such short duration that we might hesitate to apply the

term diathesis to it. It is for the most part an acute diathetic disease produced quickly and quickly cured. In saying this, however, we have not said all, for there are cases in which scurvy passes into the chronic form and becomes the source of permanent ill-health. When it does so it may fairly claim to rank with the diatheses, and it is quite possible in exceptional instances some degree of influence from it may be hereditarily transmissible. In scrofula, rickets, and in scurvy, we have examples of diathesis produced by defective food, whilst in leprosy and gout we illustrate those due to some excess, or rather to something deleterious contained in the food. Close by the side of leprosy I ought to mention ergotism, pellagra, and chronic lead-poisoning, and some others, but time does not permit. Can the specific animal poisons become the producers of permanent diatheses? This question must, I think, be answered in the main in the negative. Unquestionably they may produce conditions of ill-health which persist for a certain time, and may cause various morbid manifestations; but these states are short-lived, and perhaps are as fitly ranked as dyscrasias as diatheses. This is true even, I think, of syphilis, the most chronic and most persisting of all specific fevers. Excepting in some very small degree of reduced liability to the influence of the same poison which is to be observed in the offspring of those who have suffered, I doubt whether in any case the influence of a specific fever in a parent is to be traced in the offspring. No state of health which is heritable is ever produced. Some few exceptions to this should perhaps be allowed when small-pox, measles, and the like appear to intensify the diathesis of scrofula, but they are probably of but little importance. The general law certainly is that a specific animal poison may breed in the blood, and may for the time produce most violent disturbance of the health of the individual, but its effects cease after awhile, and cease completely, and leave the body unmodified with the exception that it is no longer liable to the influence of the same poison. This immunity lasts only during the life-time of the individual, and cannot be transmitted excepting in an exceedingly slight degree. Even in the individual it is by no means complete or invariable. I am aware that there is an apparent exception to all this in the case of syphilis. I will speak of that directly, and will also say a few words as to the limitation of the law of immunity of the individual. Before we pass to those topics, however, it may be well to ask attention to the strongly-marked differences which are to be observed between the states of health produced by the specific poisons and those which are due to inflammation from non-specific causes and which come under the law of intensification by habit. In the development of such inflammations as those of erysipelas, diphtheria, elephantiasis, especially when not due to contagion, the constitution of the individual takes a large share, and the mere fact of their occurrence reveals his previous proclivity. The disease originates, in part it is from without, in part it is from within. It is not an instance of intrusion, but of development, and the peculiarities of blood, tissue, or of nervous system are exactly those which are capable of increase. In the case of the exanthem, however, the body of the sufferer is in the main passive, and is acted upon by a poison which is intruded from without, and to which *nilens volens* his tissues must submit. The occurrence of the exanthem reveals nothing and intensifies nothing. It is from first to last a violence done from without by an external agent, and when its direct effects are over, the body may be supposed to return in all other respects to its original state. A man who has been set in the stocks is not especially likely to acquire the habit of going to sit there, nor does the man who has been burned, or who has broken his leg, there form any tissue proclivities. His tissues were in no sense consenting parties, and the laws of habit do not come into play. The possibility of second attacks and the absence of protection to offspring are facts which indicate that influence is only of transitory duration. As regards the life-long immunity of the individual conferred by an attack of an exanthem we may

probably assume that it is neither complete nor universal. Modified attacks may occur repeatedly in the same person, nor are second and fully developed ones unknown. Thus it is, I believe, a matter of general creed in the profession that when scarlet fever is in a house those who have gone through it before are liable to suffer from sore-throat without the rash, and that with measles catarrh may in the same way denote a minor degree of protection. The modification of variola by vaccination, and also the limited duration of immunity, confessedly are facts too well known. Second attacks even of variola itself may after a series of years occur. Remembering the length of time during which the effects of the syphilitic fever may persist, we might perhaps expect that it would prove more constantly protective than the others. But the facts prove that we must not conjecture, but be content to observe. No one has, I believe, even categorically denied the possibility of second attacks of syphilis, but the opinion which almost universally prevailed a few years ago came very near to this conclusion. That, however, second infections with modified results are tolerably common, and second attacks with full development of all the phenomena not extremely rare, is, I feel, more the truth. I have recently had under my care at one time three patients in whom it was certain that they were passing through second attacks. In more than one instance the patient has been under my own observation during both attacks. One of those which I have just referred to is a very remarkable case, on account of severity of both attacks. The patient, now a surgeon, of almost 45 years of age, had syphilis when a student. It was attended by a free rash, and was followed by various sequelæ, which he did not get rid of for three years. Then he married, and he now has healthy children. In the beginning of the present year he obtained by some accidental inoculation a chancre on the lip. It became very large, much indurated, and was attended by large glandular swellings. Subsequently a most copious eruption followed, and both in primary and secondary phenomena the case was as severe a one as I have seen for a long time. It may be that idiosyncrasy has something to do with this exceptional occurrence of liability during the individual's lifetime. In one instance in which I attended a member of our own profession, thrice for syphilis, first when a student, and secondly, ten years later, the same person had, he assured me, twice had variola. In respect to vaccination, it is, I believe, well recognised that some persons lose its protective power much sooner than others. Those who, by an attack of an exanthem remain protected through life, may be said in some sort to have acquired a diathesis. It is one, however, which, as I have already asserted, does not manifest itself by any active phenomena, nor is it one the influence of which extends to offspring; or if it does so, it is to an extent so small as to be almost inappreciable. It is a remarkable but undoubted fact that *quoad* the specific fevers the offspring of protected parents starts afresh. It may be, and probably is, the fact that in successive generations the tissues become to some extent habituated, and suffer less severely, but still they do suffer, and nothing approaching to immunity is perhaps ever observed.

I have been speaking of the non-inheritance of the negative diathesis induced by an attack of any one of the specific fevers, but it remains yet to say a few words as to my assertion that some of them produce an active diathesis which is heritable. The only exception to this which will be alleged is syphilis. I shall be asked "Is not the diathesis of syphilis often transmitted from parent to offspring?" No, certainly not. It is not the diathesis which results from the disease, but the germs of the disease itself that particulate elements of the virus which are transmitted. It is transference, a form of contagion rather than hereditary transmission, which occurs. Two years ago I produced before you at some length the facts which point to this conclusion. Since then, by further thought on the subject and the accumulation of more evidence, my opinions on this subject have been much strengthened. We well know that the danger of trans-

mission to children has reference not to the state of health of the parents, but to the lapse of time which has occurred since the primary disease. We see cases in plenty in which parents whose children have been quite healthy subsequently afford conclusive proof that the diathesis still persists in themselves. Indeed, it is almost an acknowledged law that parents in the late tertiary stages do not transmit taint. On the contrary, when offspring are born in the secondary stage of the disease, especially in its early periods, it is a rule with exceedingly few exceptions that the disease is transferred. These facts strongly favour the belief that the inheritance of syphilis so-called is possible only while the fluids of the parent contain the living elements of the virus. These elements, in a large majority of cases, develop and go through the same stages as if inoculation had occurred at the time of birth. It is far more like contamination *in utero* than true inheritance. By contamination in this use of the word I mean that with sperm or germ of either or of both parents there passes the virus itself, the sperm or germ being itself unmodified, but simply the material medium of transference. In the case of the mother we know well that it is not necessary that the germ should have been infected at all, but that if her blood receive the virus even so late as the eighth month it will pass into that of the child also. Inherited syphilis, when produced under these last-mentioned circumstances, runs exactly the same course as when derived from a parental taint which existed before conception. A child then inherits syphilis in precisely the same sense and in precisely the same manner as it inherits small-pox. It inherits not the diathesis, but the disease. The reason why the inheritance of small-pox is very rare, whilst that of syphilis is unfortunately common, is simply that the period during which the virus is extant in the blood is very different in the two cases. The conspicuous facts, then, with which we are all so familiar in reference to the syphilis of infants afford no proof that the diathesis of syphilis any more than of the other exanthemata is capable of transmission. It remains, however, for us to inquire whether there are other facts of a somewhat different kind which support the view which I have endeavoured to combat. I am alluding, of course, to the old controversy as to whether some forms of struma, and especially such diseases as lupus, may not be modified forms of inherited syphilis. My own belief is very strong indeed to the effect that they are not, but the facts are very detailed and very difficult to marshal concisely. My argument, if I have made it plain, has pointed to the conclusion that no minified transmission of syphilis is possible, that the child gets either nothing at all or the germs of the disease, and that in the latter case they will, subject to the laws of idiosyncrasy, develop in all cases. Excepting as the result of vaccination or of a previous attack we know nothing of inherited small-pox, and it is probably the same with syphilis. Let me try briefly to state some facts on this question, and I will then leave it to your judgment. Nothing is more common than for parents who have themselves at some former time suffered from syphilis, to produce children who remain through life robust and in perfect health. Sometimes one or more of the family inherit syphilis, and suffer, it may be, severely, whilst others, and younger ones escape, and when this occurs the latter enjoy almost exceptional vigour. When I have seen a whole family of grown up children, the offspring of syphilitic parents, manifesting signs of cachexia, there has usually been reason to think either that all had actually suffered, or that the symptoms present in some were not specific, but due to other causes. I have seen very numerous cases of lupus on the one hand, and of inherited syphilis in young persons on the other, and I never found the two things together, nor have I ever recognised in the subject of true lupus the brother or sister of one who had suffered from inherited syphilis. Of the cases of lupus which I have seen, in a very great number there were the strongest possible reasons for denying the probability of syphilis in the parents.

I have of course occasionally seen inherited syphilis and scrofula together in the same patient, but a large majority of those who suffer from the former never show any tendency whatever to the latter. In what I have said above I have been speaking of course of common lupus, and have wholly excluded that form of destructive ulceration which is sometimes mistaken for lupus, but which is from beginning to end syphilitic, and is curable by specific treatment. I have taken lupus as being a type of disease, but what I have attested as regards it applies equally to other forms of scrofula, to psoriasis, and other diseases, which have been suspected as the remote consequences of specific taint. I believe that the domain of inherited syphilis is just as definite and just as restricted as that of the acquired disease, and that it stands sponsor to none but its own progeny.

THE TEACHINGS OF TWO HUNDRED AND FIFTY YEARS OF SMALL-POX IN LONDON—FROM 1629 TO 1880. (a)

By WILLIAM A. GUY, M.B. Cantab., F.R.C.P., F.R.S.,
One of the Hon. Presidents of the Statistical Society, Consulting
Physician to King's College Hospital, &c., &c.

(Continued from page 67.)

FROM this time forward, I shall make use of the ratios I have just indicated, deaths by small pox to 100,000 by all causes, deaths by small pox to 100,000 persons living.

I will remind you again of the high mortality by small pox which prevailed up to the very close of the 18th century. In 1796, the highest figure ever recorded made its appearance; it is 18,394 in 100,000 deaths from all causes; and in the year 1800, counting that year as the last of the 18th century, there was an epidemic of the severity indicated by the figure 10,443.

In the 19th century, on the other hand, epidemics of this order ceased, the nearest approach to them being 9,592 in 1805, and 9,837 in 1871.

And here I note this interesting fact, that whereas the longest period free from epidemics of the old standard of severity (10 per cent.) in the 17th and 18th centuries, was nine years, in this 19th century the interval of the years for which we possess records was fifty-six years.

I would also take note in this place of the frequency and magnitude of the fluctuations in the figures of the 19th century, as compared with the fluctuations in measles and whooping cough, also of the wide interval which separates the highest figure from the lowest—9,837 from 56!

Compare this with the highest and lowest figures of the 18th century. The highest was 18,394, the lowest 1,532, so that in the 18th century the lowest figure was 1-12th of the highest, in the 19th, 1 in 175.

These are remarkable figures, but we shall presently see that the figures of this 19th century—the era of vaccination—are strange figures indeed!

I will first compare the minima for the three centuries. The lowest figure in the 17th century (the years of the Great Plague and Great Fire omitted) was 1,008 to the 100,000; the lowest in the 18th was 1,532; the lowest in the 19th was 56!

Let us next compare the maxima. In the 17th century the highest figure was 12,440; in the 18th, 18,394; in the 19th, 9,837. So that the highest figure in this 19th century was not greatly in excess of the half of that of the 18th.

This fall from a higher to a lower level is, as I have already stated, the reverse of what happened with measles and whooping cough.

These striking contrasts are almost sufficient in them-

selves to prove that in the case of small pox we are dealing with some force or forces which are inoperative on two other maladies of the same class.

But I will not rest content with the presumption these figures afford—I will carry the matter further, and, with this view, I have prepared a table, which will form part of the paper to be published in the next number of the *Journal of the Statistical Society*.

It is divided into three parts, and relates throughout to the two epidemic maladies *Small Pox* and *Measles*. The crosses mark transitions from lower to higher figures. They are numerous both in the columns relating to small pox and in those relating to measles, but somewhat more numerous in the case of measles.

The three parts or sections consist—First, of the facts of the last two quinquenniums of the 18th century; secondly, of the facts of the first six quinquenniums of the present century; and thirdly, of the facts of the last eight quinquenniums of this century.

The two quinquenniums of the 18th century are remarkable for the high figures they display; on these I have already sufficiently commented.

The six quinquenniums of the first part of this century represent thirty years free from any complication which sanitary reforms and improvements might be the means of introducing. It was a period of vaccination encouraged and assisted.

The eight quinquenniums ending with the recent date 1880 mark a period of forty years during which vaccination was first assisted and encouraged, then rendered compulsory, but during which period sanitary reforms and improvements were at work side by side with what I may venture to call vaccination-development.

Now there is an obvious difficulty in dealing with the figures of these two groups of quinquenniums. The first group of six quinquenniums happens to have its maximum in one year of the first quinquennium, whilst the maximum in the second group of eight quinquenniums does not occur till the 7th quinquennium. There is only one comparison, therefore, open to us. We may compare the maxima with the minima, disregarding the times of their respective occurrence. These are the figures which issue from this comparison:—

During the first six quinquenniums, the highest figure was 9,592, the lowest 2,136, showing a difference of 7,456 deaths by small pox in the 100,000 deaths. During the last eight quinquenniums, the highest figure reached was 9,837, the lowest 56, a difference of 9,781. During the first three quinquenniums of the eight, the highest figure was 3,529, the lowest 351, difference 3,178. During the last five of the eight, the highest figure was 9,837, the lowest 56, difference 9,781.

I have thought it possible to improve upon this arrangement thus:—

I divide the fourteen quinquenniums into two groups of seven each, both of which have maxima differing little from each other, namely 9,592 and 9,837, and I get these results. The maximum in the one case being 9,592, the minimum is 792, or 1-12th; the maximum in the other case being 9,837, the minimum is 56, or 1 in 175. Making every possible allowance for the fact that the sixth and seventh quinquenniums of the first seven are separated by ten years of no returns, we have nevertheless a most curious contrast, the minimum in the earlier period as large as 1-12th, that of the later period so small as 1-175th. Whatever force, or forces, then, were in operation in the first seven quinquenniums, acted with a fourteenfold power of mitigation in the second. These, again, are remarkable facts. Sanitary reform had no existence in the first seven quinquenniums. It came into existence in the first quinquennium of the last seven (in 1867), and whatever force or influence it had went on increasing as did the force or influence of vaccination itself. Sanitary reforms and improvements had no existence in the first thirty years of the century, when small pox underwent great abatement. Is it necessary to suppose that some new force or influence must be brought into

(a) Abstract of the paper as read before the Statistical Society.

play to account for the more considerable abatement of the last forty years? Let us assume for a moment, and by way of argument, that sanitary reform was this new force, and see whether we can bring the assumption to the test of figures.

Sanitary Reforms.—Sanitary reforms and improvements must be assumed to exercise the same health-preserving and live-saving influence on all epidemics alike. But the figures of the table show that while the deaths by small pox were reduced from a maximum of 98 to a minimum of 1, measles, which has undergone the most considerable abatement after small pox, exhibits only the eleventh part of the effect which small pox shows. If, therefore, we credit sanitary reforms and improvements with the utmost reduction they can claim, and take away an eleventh part from the 98 parts which represent the abatement in the case of small pox, we leave 90 units out of the 98 to be accounted for by the action of some other protective power. That power I recognise in vaccination. I can see it—I can imagine it nowhere else.

Epidemics.—But the remarkable epidemic of small pox which occurred in 1871 may be brought forward as an argument in support of a desponding view of the preventive efficacy of vaccination, assuming vaccination to have been the cause of all the abatement that small pox has not shared with other epidemic maladies. I do not see in the figures any warrant for this desponding view, but, on the contrary, much that ought to reassure us.

It is in the very nature of epidemics to take us by surprise, to spring upon us with unwonted force after lulling us into security by a long repose. From 1805 to 1831, and again from 1841 to 1871, we were free from an epidemic of the magnitude represented by some figure between 90 and 100. The longest interval between epidemic and epidemic in the 17th and 18th centuries was nine years.

Let us see what occurred in the case of the plague. I use Heberden's figures. There were five great epidemics, in the years 1593, 1603, 1625, 1636, 1665; and the deaths, in round numbers, were 11,500, 30,500, 35,400, 10,400, 68,500. The least fatal of these epidemics was interpolated between the two that were most fatal. Between the least fatal and the most fatal of the five, twenty-nine years intervened—the longest recorded reprieve—and yet the Great Plague, with its 68,500 victims, burst upon our ancestors like an unexpected and unprecedented storm. Why, then, should this small pox epidemic of 1871 surprise or appeal us? Why should it shake our faith in the protective power of vaccination? If the storm of 1871 alarms us, ought not the wonderful calm of the three successive years 1873, 1874, and 1875 to reassure us? Surely I do not put before you an improbable explanation of the facts when I say that I see in the epidemic of 1871 only a proof that there are states of atmosphere for which we have no measure, and possibly never shall have, which laugh to scorn even the protective power of vaccination, but which, having spent their mysterious force, allow that which is a real, efficient protective in all ordinary states of atmosphere to resume its protective away. The storm of 1871, which was measured by the figure 98, completely exhausted itself in the following year, when its remnant of force was measured by the moderate figure 25, leaving behind it a dead calm, lasting through three successive years, of which the measure is 1.

I make no apology for using figurative language. It expresses my meaning as clearly, but with more force, than more prosaic terms would do. I believe in vaccination as a protection against small pox, but a protection of which the force and efficiency is measured by two factors—its own virtue (whatever that may be), and the vigour of the attack directed against it by its atmospheric assailant. In most years, vaccination is victorious; in some, it is defeated.

The Protective Power of Vaccination.—This subject of vaccination and its protective power is—need I say it?—no new subject of thought with me—no new topic on which to expend language which some may deem exagger-

ated. When lecturing, some years ago, on the great epidemics which had afflicted us in times past, but had suffered extinction or abatement, I spoke of the life-long labours of our great statist, John Howard, who banished the worst forms of fever and the confluent small pox from our prisons as the *Romance of History*, and, later on, of Jenner's great discovery as the *Romance of Science*. (a) Was I guilty of exaggeration? I think not. Small pox in this great city, with its constant influx of strangers from every part of the world, with its tramps and vagrants mustering by hundreds round the open doors of our workhouses night after night, bearing with them their rags, their diseases, and their vices—small pox, among a population such as this, reduced in three successive years almost to a vanishing point, to a little more, or much less, than 1 in 1,000 (59 in 100,000 deaths)—small pox so reduced seems to me to warrant the strongest language I can use. I have shown that sanitary reforms and improvements can be credited with but an insignificant fraction of this strange result. If vaccination is not to be credited with the remainder (with 9-10ths, at least, of the whole reduction), I am at a loss to imagine what is.

But in expressing myself thus strongly, I trust that I shall not be misunderstood—that I shall not impair the value of the figures I have laid before you. I began this paper by saying that I was not influenced by the spirit of controversy. I say so still. If I may give a name to the spirit in which I have been working, I should call it a spirit of scientific curiosity. I wanted to know what my long array of figures would confess if put to the torture of a rigid scientific inquiry. My primary object was to learn what I could about small pox, and then, if the knowledge so acquired seemed to have any bearing on inoculation, or on the one simple question of the preventive efficacy of vaccination, to make application of it to that question. Again, that I may not be misunderstood, I must say that my inquiry does not extend beyond the simple question upon which alone my figures enable me to throw light. Has vaccination, as it has been actually practised, reduced the deaths by small pox? To this question, I submit, our discussions should be limited this evening.

If what I have just stated appears to any one to be inconsistent with what I have elsewhere said and written in favour of vaccination, I would point out the wide difference which there is between the feelings which we share with the outside public and the scientific indifference which we constrain ourselves to feel when, as Fellows of the Statistical Society, we address what I venture to term our constituency. In this spirit of scientific indifference I have written throughout, and I have deemed it a duty I owe the Society to place before it all the results, without exception to which all the inquiries that have suggested themselves to my mind have led me. Whatever the outside public may think of the saying that "anything may be proved by figures," we know that it is true only of the careless, the unpractised, and the dishonest: it is not true of us. Two things, at least, figures cannot be brought to prove—that the wonderful reduction which has taken place in the mortality of small pox owes nothing to vaccination, or much to sanitary reforms and improvements.

OUR LAST WAR IN EGYPT MEDICALLY CONSIDERED.

By Surgeon-General CHARLES A. GORDON, M.D., C.B.,
Late in Medical Charge of Her Majesty's Forces in Madras, and
Special Commissioner during the Franco-Prussian War.

It is considered that in reference to the expedition now being despatched to Egypt, much that is useful, in a medical sense, may be gained from a study of past experience. According to the "Medical Sketches" by Sir James McGrigor, the force which in 1801 reached Egypt from India, after descending by the Nile from Girgê, namely, a

(a) See "Public Health Lectures," VII. and VIII.

distance of nearly four hundred miles, were placed partly in quarters at Ghiza, partly in camp on the island of Rhoda. During the passage down the river the troops had almost entirely recovered from dysentery and fever, with which, while crossing the desert from Cosseir, and stationary at Girgê, they were affected; and when, on the 12th of August, they disembarked, "they were uncommonly healthy." But this state continued only a very short time after landing. In the course of the first week most of the corps sent one-twelfth, and some one-tenth, of their strength to hospital; within three weeks the number of sick had increased to a serious extent. A considerable number of cases of ophthalmia occurred, but the prevailing disease was fever. The latter affection became so general in every corps that very few persons escaped it. The attack, however, was generally of short duration, seldom lasting more than two to five days, and being rarely fatal. Ghiza was considered to be an unhealthy quarter, and the encampment on Rhoda was found to be swampy. The sick of the army were therefore sent into Ibrahim Bey Fort, pleasantly situated on the Cairo bank of the river. The circumstance having transpired that shortly before the arrival of the British the French had some cases of plague in a ward of that hospital, "every measure of precaution was taken, and the disease did not spread." [And yet the tendency of the present day is to assert that in bygone times hygiene was a thing unknown in the army.] It was remarked, however, that few of the patients sent to that hospital escaped the prevailing fever altogether. During the month of August the range of the thermometer in the hospital was between 80° 5' F. to 90° F. The ratio of sickness among the troops was very considerable, mortality was relatively small, and many of the deaths could be traced to the situation near Cairo [which may be cited as another proof that the influence of locality on disease was quite understood by army surgeons of that day]. Dysentery now prevailed to a considerable extent, and ophthalmia was very general. Hepatitis did not appear.

Early in September the greater part of the army had removed to and encamped near Rosetta. Separate regimental hospitals were provided for every corps at that place. [This measure presumably adopted as an improvement on the general hospital as it existed in Fort Ibrahim at Cairo. The circumstance is therefore of importance in reference to the system of hospitals recently reintroduced in the British, and, indeed, the army of every other European nation.] Sickness now increased rapidly among the troops, principally ophthalmia, dysentery, and hepatitis. Now, another and still more serious disease appeared, namely, plague. The first case of this nature occurred on the 14th of the month (September). Very elaborate measures were at once taken with a view to the isolation of further cases, and to the prevention of the spread of the terrible disease. "Our situation on the 16th, that is, two days afterwards, now became very alarming." The hospital of the 88th Regiment, and the "observation room" attached thereto were thoroughly disinfected by means of nitrous fumigation. A large building was procured, "and with all possible haste the men were moved into it." [What more efficient disinfectant could be employed at the present time?] All the men before removal were bathed, their hair cut, their clothes taken to be washed, and afterwards clean clothing and bedding given to them, those used by them being "repeatedly washed and baked."

So excellent were the results of the means thus indicated that only one instance of the Plague appeared in the new hospital. [Could more complete results be ensured even now-a-days?] The weather during September continued as it had been in August. There was no rain. On the 15th the Nile began to recede. On that day, as also the 16th and 17th, the wind blew from the westward. After this the weather was close and calm. The general range of the thermometer in a house in Rosetta was from 73° Fahr. to 83° 5' Fahr. The prevailing diseases among the troops were ophthalmia, dysentery, and hepatitis.

THE CHINESE MATERIA MEDICA.

By FREDERICK NEWCOME, F.S.S.

(Continued from page 24.)

Chien'hu is a cheap and somewhat largely cultivated medicine, and is, we believe, the shoots of a variety of *Bupleurum*, just as Ch'ai Hu exported from Newchwang in the north, and Wuhu in the interior, are the tender shoots of the *Bupleurum Octoradiatum*. Hsi Hsin is another drug in which a substantial trade is carried on. It appears in the list of several very distant ports, and we may therefore conclude is common to the whole, or greater part, of the equatorial zone. It has been distinguished as *Heteropa asaroides*. Fang-fêng, root of *Libanotis* is likewise a generally consequential product; and so is Ma' Huang (*Ephedra flava*). The same again may be said about Mu' Tung (*Clematis vitalba*); Wu Wei-tzû (*Kadsura Chinenensis*); Huang Pai the bark of *Pterocarpus flavus*; and Ch'ê Ch'ien tzû, the seeds of *Plantago major*. T'iao Ch'i is likewise not unimportant, but its source is still incognito. Two or more kinds of pœony are found serviceable—the root of *Pœonia rubra* from which a medicine named Ch'ih Shao is educed, and *Pœonia albiflora*, from whence Pai Shao. Among other herbs turned to account are the roots of Gentian or Dragon's Gall Plant. From these, found in several districts, a medicine called in the native vocabulary Lung Tan-ts'ao, or Tants'ao, is derived. Somewhat curiously, the *Pekin Gazette* contained a notice the other day to the effect that 5 catties of this medicine had been purchased for the especial use of His Sublime and Imperial Majesty. Next, we have *Equisetum hyemale* (Mu Tsai), rough horse tail or Dutch rushes, once used by whitesmiths and cabinet makers here for polishing metals and wood; also by dairymaids in the north to scour their milk pails. *Cicuta* (whence Kao Pên) the water hemlock, drunk by Socrates; *Amomum amarum* (I Chih) a species of ginger, and supposed to have formed one ingredient in the dose given to a member of Earl Macartney's embassy by a native physician, who, attributing his patient's illness to the predominance of cold humours in the system instead of to a severe dysentery, the true cause, prescribed an admixture of cayenne pepper, cardamoms, and ginger, given in hot distilled spirit, with the necessary sequel of as nearly as possible settling the unhappy European.

Huang Pai (*Pterocarpus flavus*), mentioned above, is the bark of a tree similar to that found in Brazil, from whence the red saunders-wood of the cabinet maker is obtained. It is utilised to a considerable extent by the Chinese, to whom its dyeing properties are well known, if not greatly appreciated. The root of Bellwort (*Platycodon grandiflorum*), found co-existing in both the northern and southern provinces, is another drug admired under the name, Chieh Kêng; while of the many species of convolvulus with which the country abounds scarce one can be named that is not turned to some medicinal account or other. Chin Yin'hua consists of the flowers, stalks, and leaves of the *Lonicera Xylosteum*, a native of the north, and is exported from Newchwang. Mentioning this plant naturally directs attention to the many uses to which aloe wood is put by the Kitata. The agalocha or Xylo aloe forms a regular element in the Oriental materia medica, being esteemed a sovereign cordial in fainting fits or disorders of the stomachic region, also as a vermifuge for children afflicted with ascarides. It is likewise used as a restorative in palsy. However, its chief value is as an incense to burn in the Temples of Budda, or for scenting rooms or clothes. Still far from cheap, it was at one time excessively costly, the calambac or heart being positively dearer than gold. A species of skull-cap (*Scutellaria Viscidula*) is largely consumed under the cognomen Huang Ch'in, but for what particular purposes it is employed we are unaware. Meadow rue (*Thalictrum rubellum*) is also included in the native pharmacopœia under the name Shêng Ma,

and so is Dodder (*Cuscuta*) under that of Tu Sati-zü. Of this last medicine a considerable quantity is produced, nor does its cultivation seem confined to any particular district. The truth of Sir George Staunton's dictum, about the Chinese having in the course of ages found a medicinal duty for every product of the field, is borne out by the fact that the kernels of the common cherry are converted into a physic sold as Yü Li-jên. Among other drugs Chi Shêng has been recognised as the *Epiphytes*; Fang Chi, as a variety of convolvulus; Pai Fu-tzü as the *Aroideæ*; while Tzü 'Hua is supposed to be the flowers of a species of Hollyhock (scientific name unknown), and is used both as a medicine and a dye, chiefly the latter. The origin of Hsien P'i, Ta 'Li-tzü, and Taio Ch'i, are still involved in obscurity. None of the last-mentioned medicines, except T'iao Ch'i constitute at all consequential elements in Chinese medical economy.

Curiously enough the Chinese attach but small importance to that most valuable of roots, rhubarb. In so far as they themselves are concerned, other drugs take its place, although it seems beyond dispute that at one time they were of opinion that if supplies were cut off the detested foreigners of the north would all die of constipation. This anecdote is well vouched for; indeed, prior to the outbreak of war in 1839-40, the terrible threat was actually held out, Lin, or Keshan (the same Ki-chan subsequently met with by the Abbé Huc at Lla-Saa, Thibet. This statesman was not executed, as commonly supposed, for ceding Hong Kong), we forget which, was so firmly persuaded of the fact as to memorialise the Emperor regarding the advisability of forbidding the export of rhubarb, and thus starve the foreigners into submission. But dropping anecdote, rhubarb grows wild in all the northern and western provinces, yet nowhere does it seem to be brought under cultivation, invariably being found in a wild state. Several varieties of rheum plant are indigenous to China, some being inestimably valuable, others almost worthless. Shênai roots are by far the most esteemed—those coming from the Kanchow district being perhaps the more prized of all. This rhubarb, the best in the market, can be readily distinguished from other kinds. The roots are large, smooth, and extremely fragrant; whereas those obtained in the province of Szechwan are smaller, rough on the exterior, deficient in flavour, and when cut give out little scent. Best Szechwan rhubarb commands only about one half the price asked for Shênai rhubarb, while inferior qualities fetch from one-tenth upwards. In this connection it is interesting to note how strongly many Chinese hold by the belief in the utter inefficacy of roots grown in the Southern provinces, which, according to their theory, are only good to sell to the English barbarians. As a fact, Russian merchants look at no rhubarb that does not bear on its face evidence of a northern derivation. In this, unfortunately, they are not imitated by their English rivals, who buy anything that is offered so long as the price is sufficiently tempting, or hold out a prospect of additional profit. This points to the necessity of medical men and retail druggists exercising extreme care in the selection of their rhubarb, and, perhaps, more important still, to buy only of persons in whose judgment and honesty they can place entire dependence.

Another good sample arrives at Tientsin from Hsining in Kansuh, after which town it takes its name. Churgh'i rhubarb is also greatly prized, while Chihuang, Taihuang, and Shanhuang, are about as worthless as well can be. Doubtless, however, as Mr. Detring remarks, a considerable percentage of inferior rhubarb is nothing more than Dock plant root, sold under the fashionable name. Upon the properties of this sham we cannot speak authoritatively, but quite likely it possesses properties similar to those of the Yellow Dock and other European species of this order. It is not exactly pleasant to contemplate that the greater part of this rubbish is bought for the English market, but such,

nevertheless, appears to be the case. The other producing districts besides those mentioned above are Chihli, Honan, and different parts of Thibet, from whence several very fine varieties, formerly sent overland, *via* Kiakhta, through Russia are obtained.

Galangal, a product of the Island of Hainan, in the Tonguin Gulf, is another largely consumed article, over 5,000 piculs being sent away yearly to Hong Kong for transhipment to Chinese ports. These roots are very inexpensive, about five or six shillings a hundredweight, and on this account commend themselves to the poor unsophisticated Chinese, who cares little about taste so long as the article is cheap. They have an unpleasant aromatic smell, and a displeasing, bitter, extremely hot biting taste. Formerly they were used in this country in bitter infusions, but on account of their obnoxious flavour the practice has died out. Kempfer says, "They were used to remove obstructions of the hypochondria, to warm the stomach, discuss flatulency, and to strengthen the bowels and nervous system." Possibly they do as much for "Ah Sing" to-day.

Sesamum seeds are perverted to a variety of purposes medicinal and otherwise; one, little known here, is worth alluding to. At Hankow the manufacture of "Lie Opium" forms a not unimportant industry, about 700 cwt. being exported yearly to Chefoo and other northern centres. This spurious opium is made from sesamum seeds mixed with other ingredients, and is used to adulterate the genuine article. It is indiscriminately known, according to Mr. George Hughes, of Chefoo, as Chiayên-Kao, preparation of false opium; Liaoping, cakestuff; and Chihma-Kao, preparation of sesamum seed. While on the topic of adulterants it may be worth while to direct the attention of the medical profession to a leaf known as Kêncha, or Kên Ch'a in the native tongue, and *especially prepared for adulterating tea*. From the port of Kiung-chow, in Hainan, 2,791 piculs (372,000 lb.) were exported to Hong Kong in the year 1880. In the year previous the quantity was only 751 piculs, and a few years ago, nothing at all. This fact, and the destination Hong Kong, suggests the not very pleasing possibility that most, if not all, of the 372,000 lbs. of Kêncha ultimately finds its way to England to the questionable benefit of Her Britannic Majesty's liege.

Camphor is likewise grossly adulterated with a glue obtained by boiling a rattan creeper, locally called T'êngtsai. This weed, growing luxuriantly in the interior of Formosa from whence, as everyone is aware, all Chinese camphor is derived, is full of a glutinous matter which boiling water converts into a colourless glue. Mixing this with the pure camphor and a small percentage of water prevents evaporation, though naturally destroying the high quality of the article itself. Camphor so adulterated will keep, it is said, for a couple of months without loss; indeed, will bear the journey to Europe without suffering appreciable diminution. Experiments recently made have demonstrated the existence of two parts of glue to three of camphor in certain samples offered in the Tamsui market, rendering the article absolutely useless. Happily fire will readily detect the foreign body. Mr. Walter Lay, to whose admirable report upon the camphor trade in 1880 we are indebted for this information, adds: "I have obtained a sample of the plant from which the glue is obtained, but cannot find out what its botanical name is; indeed, I have not succeeded even in obtaining the correct Chinese characters for it. It is called locally T'êngtsai, but it doubtless has a more distinctive appellation than that. It is not given in the 'Topography of Tamsui.' Mention is made in the Wahu Report for 1878 of a plant which yields a glutinous substance on being boiled in water, and which is used in the manufacture of paper. The name given to it at Wuhu is Yang Kout'êng, and this possibly may be the name of the creeper used here for the adulteration of camphor."

Before the ruthless axe of the Chinese woodcutter the

beautiful inland forests still adorned by the graceful *Laurus camphora* are fast disappearing. The aborigines inhabiting the interior fight desperately for the possession of their woods, but each year sees a fresh tract surrendered to their indomitable enemies. To illustrate the difficulty attending the collection of the prized wood, it may be mentioned, on the authority of the above-named gentleman, that between five and six hundred Chinese were killed two years ago in the petty warfare which prevailed with the savages. Sooner or later there must be a dearth of camphor. With their customary want of common prudence the conquering race are recklessly clearing the ground for tea cultivation, burning up the camphor wood in tea-firing operations, for which purpose it can seemingly be used with perfect safety, despite the pungent fumes given forth.

Very little of the camphor manufactured in Formosa is consumed by the Celestials, nearly all being shipped to foreign countries. On the other hand, they continue importing for their own use the more precious natural article secreted by the *Dryobalanops camphora* of Sumatra and Borneo. For these concrete masses, commonly known as Camphor Baroos, fancy prices are still paid—thirty-one shillings a pound was the import price at Ningpo last year. Of this fine camphor, it may be added, but a small quantity finds its way to Europe; the relative cheapness of the manufactured article driving it quite out of our markets, although it is well known the native manufacturers in Formosa place no special reliance on their own product, which, they say, possesses little or no virtue—very little now-a-days, one may opine, if adulteration is carried on to the extent asserted.

(To be continued.)

Clinical Records.

GLASGOW OPHTHALMIC INSTITUTION.

Restoration of Eyelid by Transplantation of Skin Flap from Distant Parts by Wolfe's Method.

By A. T. THOMSON, M.D., C.M.

THE interesting paper read recently by Dr. Benson before the Surgical Society of Ireland, and the discussion thereof, published in the *Medical Press* of April 26th, 1882, induces me to send the following record of a case in which I assisted Dr. Wolfe in the performance of a similar operation.

A. McD., et. 65, was admitted 1st July, 1882, into the Glasgow Ophthalmic Institution, suffering from epithelial cancer involving half of the upper and half of the lower eyelids of the left eye, and extending slightly beyond the inner canthus to the nasal integuments; the lower lid was puckered, and everted by the neoplasm. On the integuments of the forehead and cheek were scattered, warty, and melanotic nodules, and, therefore, rendered quite unsuitable for flap formation.

Operation—On 4th July Dr. Wolfe performed the operation as follows:—Under ordinary circumstances, when the ectropion is caused by a burn, he first makes a staphylorrhaphia, and dissects and removes the adherent integuments and hardened tissues to make a clean bed for the new skin flaps, but in this case, owing to the diseased and touch-me-not condition of the parts, he introduced a bony spatula under the eyelid and carefully dissected off the affected portions by means of a scalpel and curved scissors; the wound was thoroughly cleansed with warm water and wiped perfectly dry. The required quantity of skin measuring 2 + 1, was removed from the radial aspect of the left forearm, allowing sufficient latitude for shrinking; every vestige of subcutaneous tissue was removed from its under surface by the scissors, leaving a pure white surface; it was dipped into tepid water and gently dried, and then placed over the wound of the lower lid, inner canthus, and also part of the upper lid, leaving a portion of the latter to heal by granulations. Pieces of lint wrung out of hot water were placed over the part; above these dry lint (covering both eyes), a piece of oiled silk, and an immovable bandage, completed the operation.

The same kind of dressing was renewed on the fourth day, and every day subsequently. There was no discharge from the wound, and the transplanted skin presented a healthy appearance, only, the centre was whiter, the rest was of a rosy tint, and adhering in every part to its new site.

July 24th.—Patient discharged cured, twenty days after the operation, the lids are freely movable, and the eyeball completely protected.

Remarks.—Dr. Wolfe in his first operation, published in the *British Medical Journal*, September, 1875, dissected the skin of the face all round, which served as a frame, under which the new flap was inserted, and by which it was held in its place without ligatures. The dressing consisted of dry lint and cotton wadding impregnated with the fumes of carbolic acid, the result of the dressing had this effect, he thought, of causing the cuticle to peel off. In subsequent operations, he tried four silk ligatures, but found now and then a small suppurating spot where the needle punctured, and has ultimately come to the conclusion that, simple coaptation with warm water dressing is more suitable for the maintenance of the vitality of the flaps.

I may remark in conclusion that, it appears to me that Dr. Benson and some members of the Society in discussing the comparative merits of this operation, have not sufficiently appreciated the extent of its applicability: their opinion seemed to be that the operation should only be resorted to in cases where the neighbouring parts, as face, forehead, &c., are unsuitable for gliding or twisting flaps; but, from the cases which come under our notice, and indeed it is only the other day we saw two operations for ectropion, one, done by a very competent surgeon, but, the puckering of the lid, dragging of the parts and resulting scars left, show that such results are not to be compared with the clean and elegant appearance presented by Wolfe's operation.

The eight cases recorded by Dr. Benson and just alluded to are the first performed in this country since Dr. Wolfe introduced the operation; and, considering the difficulties connected with its proper performance, and some misconceptions which still attaches to it, the results may be regarded as highly satisfactory. But, when its adoption will have become general, and the procedure has undergone improvements, there is no reason to doubt that it will occupy a far higher place in the estimation of the profession.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

ORIGIN OF SCROFULOUS WHITE SWELLING.—At the meeting of the Société de Chirurgie M. Launelougue made a communication upon the character and origin of white swelling, called scrofulous. He showed that the tubercle was the commencement of all the lesions attributed to this affection. The elements that formed the fungous growths were specific, for they were inoculable. He succeeded in inoculating eight rabbits with the morbid element, thus tuberculous and scrofulous arthritis should no longer be described separately, as there exists but one form, namely, the tuberculous. As to the different parts of the articulation affected with tubercle M. Launelougue believed that the cartilage was wholly exempt, although such was not the general opinion, the synovial was frequently the first to be affected, but it was in the bone in general that the first sign of the disease manifested itself. The alteration in the bone was either circumscribed or diffuse in which case the whole epiphysis was implicated. The disease afterwards invaded the synovial, and soon the other epiphysis became attacked. In the latent state when the synovial is but slightly affected, and the epiphysis barely sensitive, it would be rash to interfere, for the exact position of the lesion is not known; rest with a fixed position of the limb and good nourishment is all that would be necessary. If the membrane be attacked, a good compression on the igni-puncture, with

perhaps interstitial injections of tincture of iodine or iodoform will give good results. When there is an abscess it must be opened at once, and the tubercle carefully sought for and taken away by scraping, gouging, or resection, partial or total when necessary. M. Verneuil agreed in general with the statements of M. Lunelougue, but he believed there was a third variety of the disease in question, which he observed in the adult, and which could not be attributed to the presence of tubercle or inflammation. The form he alluded to resembled a well developed hydrarthrosis with a sense of fluctuation, but without any sign of inflammation or caseous lesion of any kind. Cure is effected by fixing the limb, compression, and application of iodine.

ANTISEPTIC PROPERTIES OF OXYGENATED WATER.—At the Hôpital St. Louis M. Péan has been making experiments on the antiseptic properties of oxygenated water. This water was specially prepared, and contained from two to twelve times its volume of oxygen. Externally, the liquid was used in the dressing of large wounds and ulcerations of every kind, and having given good results it was used as the only dressing after major operations, such as amputations of the arm, leg, and thigh, and in the ablation of large tumours. During the operations a spray of the same liquid was playing on the wounds. Under the influence of these applications the wounds showed a favourable tendency to unite by first intention, and in the case of chronic ulcers cicatrization was observed to be effected more rapidly than with any other dressing. At the same time to patients who had been treated by other means, and who were threatened with septicæmia the oxygen water was given internally with the most salutary results. M. Péan believes that this agent is superior to phenic acid, and it has also the advantage of being devoid of any obnoxious odour, nor does it possess any toxic properties.

ACTION OF QUININE AND SALICYLIC ACID ON THE EAR.—Dr. Kirchener has studied the action of these two medicines upon the ear in order to elucidate the question still disputed as to whether the noises in the ear are really to be attributed to congestion of the labyrinth. Clinical experience has for a long time shown that these agents produced vertigo and a certain degree of deafness which disappeared immediately on the cessation of the drug; but sometimes when the quinine or salicylic acid was given in large doses these symptoms persist and constitute a long and serious affection. Experiments on animals proved that quinine and salicylic acid produced hyperæmia of the tympanum, and when excessive, hæmorrhage might result. If the hyperæmia lasted a certain time it might cause an alteration of the ultimate ramifications of the nerve.

GLYCERINE IN PHTHISIS.—Dr. Jacoud, editor of the *Dictionnaire de Médecine et de Chirurgie*, prescribes in common phthisis, where cod-liver oil is not borne, glycerine with a certain amount of rum or brandy. Glycerine one ounce, rum or cognac two drachms, peppermint one drop, a tea-spoonful three or four times a day. This composition of an agreeable savour is well tolerated by the stomach, and excites the digestive functions.

SULPHUR IN WHOOPING-COUGH.—Dr. Luton recommends in the treatment of whooping-cough, especially in the convulsive period, the administration of sulphur. Flowers of sulphur 8 to 15 grains, sugar of milk 16 grains. In ten powders, one every two hours, carbonate of iron should be given to keep up the strength, ten grains in the day. Coffee renders good service, and a vomitive should be given every two days. Belladonna, which has been considered the most efficacious remedy in this disease, has been given by

Trousseau as follows:—Ext. belladonna four grains, syrup of poppies and simple syrup of each one ounce; one to eight tea-spoonful to be given in the twenty-four hours, according to age. Dover's powder associated with extract of hemlock has been frequently given with the best results in the formula:—Dover's powder one grain, extract of hemlock in powder one grain, ginger in powder two grains, and sugar four grains, the whole to be given at bed-time, for a child of two years.

Special.

RECOVERY OF NINE CASES OF HYDROPHOBIA.

At a recent meeting of the Paris Academy of Medicine a memorandum was read by M. Decroix reporting nine cases of cure of hydrophobia.

In the first case Dr. Menecier had inoculated with the saliva of a mad dog two other dogs and a rabbit. The three latter died of hydrophobia, while the former, which had supplied the virus, recovered.

Among the experiments on rabies which M. Decroix had made, one of them was the inoculation of a dog with the saliva of a mad dog. The latter died while the former became first mad and then recovered. M. Decroix had also inoculated, with saliva taken from a man some hours before he died mad, a dog, which became mad, but ultimately recovered.

The fourth case was one in which M. Rey, formerly Director of the Veterinary School at Lyons, received into the hospital a dog bitten by another mad dog. It became hydrophobic, but finally recovered.

M. Laquerrière, military veterinary surgeon, also reported a case of a dog which, when bitten by a mad dog, became affected with the malady, and was ordered to be destroyed; but the proprietor did not wish to lose the animal, and it recovered without any treatment.

In the sixth case Dr. Lunel had treated a reaper who went mad after being bitten by a rabid dog, and he recovered; while a dog bitten at the same time by the same animal died.

In the seventh case Dr. Nichols, at a time when both men and animals were going mad in the same locality, was called in to attend an Englishman who showed symptoms of rabies. He recovered in a few days, although he had been bitten by a dog twenty-one days before, which had not been found up to that date.

In the eighth case a mad dog bit two men, a cow, and a dog. They all died except one of the men, who recovered.

Lastly, M. Decroix reported that he had seen a horse which showed symptoms of madness. It recovered in eight or ten days, as did men and other animals similarly affected.

In hydrophobia the fits commence and increase in frequency and intensity during the first two or three days; are at their height for two or three days, and disappear in the same period of time if death has not taken place about the fifth or sixth day. The scientific men who have not seen cases which have been cured are very wrong in regarding the cases reported by those who have seen them recover, and in publishing only unsuccessful cases, or those where there has been an error in the diagnosis, thereby forming erroneous ideas in the public mind.

The Committee on Rabies made, during the year 1874, a series of experiments with medicines said to be useful for curing rabies, in which they made use of pilocarpin three times, and in every case the remedies hastened death by the violent fits they brought on.

In the course of his experience M. Decroix met with two cases of rabies which did not end fatally.

The conclusions arrived at by the Committee are as follows:—

1. It has been experimentally demonstrated that rabies may recover spontaneously.

2. Up to the present no treatment has been proved to be anti-hydrophobic, and cases of cure by this or that means may be attributed to the efforts of nature.

3. All the means used by the Committee since 1874, comprising principally injections of azotate of pilocarpin, have hastened rather than retarded the death of the subject.

4. Those dogs usually recovered which were left without treatment, as the medicines brought on violent fits, and there is an inclination among medical men to leave men thus attacked in perfect quiet, and only practise experiments on animals. The filing down of dogs' teeth—an easy and almost painless operation—is still the most efficacious preventative of madness.

6. Rabid people left in the dark and kept quiet are not subject to fits, unless they are brought on by excitement or ordinary medicines, and “as far as I am concerned,” says M. Decroix, “I would rather be attacked by this kind of madness than many other diseases, particularly than that red chancre of smokers.”

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby 8; Bradford 14; Bristol 15; Birmingham, Sheffield, Plymouth 16; London, Norwich, Wolverhampton 17; Brighton, Birkenhead, Blackburn 18; Cardiff, Halifax, Portsmouth 19; Hull, Oldham 20; Dublin, Edinburgh, Newcastle-on-Tyne 21; Manchester, Glasgow, Nottingham, Huddersfield, Liverpool 22; Leeds 23; Salford, Leicester 24; Sunderland 25; Bolton 26; and Preston 30.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 27, Bombay 21, Madras 36; Paris 22; Geneva 12; Brussels 20; Amsterdam 23; Rotterdam 16, The Hague 17; Copenhagen 25; Stockholm 27; Christiania 20; St. Petersburg 48; Berlin 29; Hamburg 24; Dresden 24, Breslau 37, Vienna 29, Prague 30, Buda-Pesth, 31, Munich 26, Trieste 29, Rome 26, Turin 30, New York 33, Brooklyn 25, Philadelphia 21, and Baltimore 38.

THE highest annual death-rates per 1,000 in the large towns last week from diseases of the zymotic class, were: From whooping-cough, 1·4 in Newcastle-upon-Tyne and 1·1 in Nottingham; from scarlet fever, 1·8 in Sunderland and 1·3; from measles, 1·3 both in Derby and Huddersfield; and from fever, 1·6 in Portsmouth and 1·3 in Sunderland. The death-rate from diarrhoea averaged 1·7 per 1,000, considerably below the mean rate in the corresponding week of recent years. Thirteen deaths from diphtheria were returned in London, 2 in Edinburgh, and 2 in Portsmouth. Small-pox caused 4 deaths in London, 3 in Leeds, one in Manchester, and one in Newcastle-upon-Tyne.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 2, 1882.

IMPOLITIC SCIENCE.

It requires but a cursory examination of anti-vivisection literature to discover from it that the principal impetus given to the movement which has, above all things, paralysed the study of experimental physiology in this country was originally derived from France. Not directly, it is true, but as a reflex of the publicity with which our trans-channel brethren have been wont to surround their method of carrying out scientific investigations; for it is chiefly owing to the unnecessary ostentation of Majendie and his school that anti-vivisection fulminades have been enriched with examples of the “atrocities” they mainly serve to emphasise. That much mischief has been caused by such unwise display on the part of professional workers is incontrovertible; indeed, we may safely assert that the crippling legislation from the effects of which English science is at present suffering would never have been carried out had it been called for only as a means of checking abuses connected with the employment of vivisection as an aid to discovery by our own countrymen. In that monument of stupidity and ignorance, the “evidence” given before the Royal Commission by a well-known opponent of scientific advance, almost the only facts adduced in support of his opposition are derived from accounts of experiments conducted in foreign laboratories. It is the greater pity, therefore, that a policy which has been so productive of evil in the past should still be persisted

in at the present, and by the living representatives of those who were formerly the instruments of disaster.

There is peculiar reason just now why no obstacle should be opposed to the steady growth of a better feeling in the public mind towards the authors of discoveries, and why every attempt should be made to educate the people to perceive the vital importance to themselves of freedom in research, while, at the same time, any cause of offence to the uneducated in this respect should, within the limits of legitimate regard for progress, be studiously avoided. There are in action at this moment several forces, each of which is slowly but surely tending to the destruction of that bitter animosity to science which, inasmuch as it was based on pure ignorance, must of necessity fall before the illumination of a better knowledge. All we who are deeply interested in the consequences that shall follow from later combats with this spirit of ignorance cannot fail to regard any interference, from whencesoever it may come, with the ameliorating influences that are at work, with the utmost jealousy, and hence it is that the term "impolitic science" is the least harsh we can find to apply to certain recent proceedings in France, which are, we fear, likely to exert a sinister influence on the progress of research principles in this country also. With a want of discrimination which, to say the least, is unfortunate, Dr. Laborde, of Paris, has seen fit to perform at a public lecture a series of experiments on living animals, for which, under the circumstances, no justification can possibly be found. We cannot wonder—indeed, we can even feel satisfied—that popular indignation has been aroused in consequence, and that an urgent appeal has been made to the Society for the Prevention of Cruelty to Animals to use its endeavours to prevent a repetition of such needless cruelty. Dr. Laborde is an earnest and a successful worker, but this fact cannot be held to excuse him while desecrating the scientific method by demonstrations the only effect of which is to excite a vulgar *furor*, without in any way advancing a single scientific question. We are, and have consistently been, enthusiastic advocates for the repeal of the vexatious law which hampers English physiologists in pursuit of truth, but throughout the whole controversy we have invariably insisted that the power of experimenting is demanded for, and should be employed for research pure and simple. Vivisectional experiments for the purpose of demonstrating well-proven points can never be defended on grounds either of utility or of necessity, and in the hands of British teachers would never be so employed.

We regret extremely that the Parisian world has been exercised by this new development of the vivisection dispute, and more especially because equal publicity obtains for all the particulars connected with it on this side also. It will, without doubt, form the groundwork for a new and vehement attack by the anti-vivisection brotherhood, which had become all but silenced as a consequence of the propagandist proceedings recently directed against it here. Opportunity, unfortunately, has once again been given them of raking up afresh the time-honoured and familiar chance expressions of innumerable scientific worthies who, at some time or other,

may have spoken or written sentences seemingly antagonistic, when taken from their context, of the experimental method. Valueless as such argument is, it carries a certain weight with those who yield obedience to a name without consideration for the utterances accredited to its owner, and hence the influence of such disjointed expressions when used by noisy agitators, who, for motives more or less pure, form themselves into societies and committees, and other associations, for appealing to the public purse.

Under circumstances like those surrounding Dr. Laborde's recent display the only result to be anticipated, even at the most favourable reckoning, is the gratification of a morbid and vulgar taste for horrors. It would be feeble to pretend that any scientific truth, or that any instruction could by this means be conveyed to a public audience which should be at all commensurate with the sacrifices entailed. The tyro or the uninitiated in science can derive no advantage from examination of experiments conducted on living animals; no advantage, that is, which might not equally well be secured by attentive study of the records of experiments on which the conclusions to be demonstrated depend. Until he is acquainted with the great principles of physiology, and until he is so far an expert in the science that he can grasp the consequences flowing from experimental interference with functions, the student is not fitted to derive benefit from them, or to date his advance from their performance. It is undoubtedly a fact of the utmost importance to know that the heart will continue its pulsations after removal from the body, but it is unnecessary to resort to vivisection for the purpose of demonstrating it. Again, the fundamental experiments through which knowledge has been gained of the specific action of drugs can never be repeated with advantage before an audience untrained to habits of exact observation; and yet we find that such fruitless and wholly unnecessary violations of right and propriety are again and again committed, and with the natural result of exciting disgust against those who commit them.

We earnestly hope that our French *confères* may be led to perceive the unwisdom of such acts as Dr. Laborde has been guilty of, and that they will recognise the absolute necessity of confining vivisectional experiments to the laboratory, where alone they can be productive of good, and where, we contend, they should be permitted with all the freedom and licence sanctioned by the vast importance of the issues at stake.

THE NOTIFICATION OF INFECTIOUS DISEASE.

THE agitation against an extension of the law by which physicians are liable to be fined or locked up if they omit to report their cases of infectious disease to the sanitarians, is growing rapidly in England. Meetings have been held in several important towns for the purpose of backing up the new "Association for preventing the extension of the system," which Association has been recently formed in Liverpool under the presidency of Dr. Carter.

We hear that Sheffield has now taken up arms against

compulsory notification, and will shortly hold a demonstration on the subject.

The attitude of the British Medical Association in reference to the matter is very remarkable, and is likely to lead to an *emeute* at the Worcester meeting. It may be recollected that last year, at Ryde, the Parliamentary Bills Committee gave a sort of indefinite promise to support compulsory notification, and that Mr. Michael, Q.C., came down from London on behalf of the Social Science Association to try to persuade the members of the Association to place themselves voluntarily under the yoke, but his effort failed; his resolution to that effect was rejected, and, moreover, the profession was, for the first time, aroused to resistance. That resistance being pressed upon the attention of the executive of the Association, a conference on the subject in London was spoken of and half promised, but it never took place, and, consequently, the members of the Association who object to be made sanitary detectives have been compelled to take their own course. Accordingly, the Liverpool Anti-Compulsion Society has applied to the Committee of Council to have a special time and place fixed for a debate on the subject at Worcester, and the Committee of Council, instead of complying with the request, has answered by relegating the discussion to the Public Health Section. It is hardly necessary for us to point out that this attempt to cushion the protest against compulsory notification is—if not illegal—utterly unfair.

Under the bye-laws any fifty members of the Association can, by requisition, call a special meeting of the Association to debate any particular question, and if this important matter is to be shelved at Worcester by referring it to a section, it will be easy to obtain the necessary signatures to such a requisition. But there is another more speedy course which may be pursued if it be considered expedient to force a debate. It will be open to any member to move an amendment to, or the rejection of the report of the Parliamentary Bills Committee, or even to move for a reconstruction of that Committee, so that those members of it who have directed its policy towards compulsory notification may be eliminated from it. Whether any or all of these proceedings may be necessary to bring the danger in which the profession stands under the notice of the entire body of members, it is evident that the opponents of the policy of the Parliamentary Bills Committee cannot rest content with a dull half-hour's talk on the subject before the Public Health section. The case for the opponents could not be fully heard by the members of the Association in any such place, nor would any decision then arrived at have any real influence on the policy of the Association; therefore, we hope, that those who are acting in defence of the profession in this matter will insist on a public hearing of their protest. The question is worthy of it, and the numerical importance of the anti-notificationists entitles them to demand the privilege of speech.

THE IRISH POOR-LAW SUPERANNUATION BILL.

THIS measure, which has been waiting for a second reading so long that its passing this session had almost ceased to be hoped for, came before the House at the extra

sitting of last Saturday week. The Irish Medical Association had only a few hours' notice of the intention to bring on the Bill, but it did what was possible to bring members to the support of it, and, after all, the second reading was very near being adjourned in consequence of the length to which the discussion on some Scotch education Bill, which had precedence, extended. In moving the second reading Mr. Herbert Gladstone promised that if the House would assent to the second reading he would propose various amendments in committee in deference to Irish opinion. He would also propose to submit the Bill to a committee of thirteen Irish members.

Mr. Healy thought the Government had taken a reasonable course, but differed totally on the principle of giving so much power to the Local Government Board.

Mr. Leamy here moved the adjournment. He opposed the Bill, and he had put down his notice of opposition in order that the Bill should only be taken when it could be properly discussed.

Mr. Daly seconded. The experience he had of the Local Government Board gave him the profoundest distrust in it, and he considered that there could be no greater monstrosity than that the tribunal that should grant men superannuation was a tribunal which had no cognisance of the individual merits or demerits of the men to whom they were granting the superannuation.

Mr. Mundella thought the Bill ought to be read a second time.

Mr. A. O'Connor suggested to the hon. member for Waterford that he should withdraw his motion. Nobody could be more opposed to this Bill than he was; but at the same time he was bound to admit that some provision should, as was proposed in this Bill, be made to meet the very scandalous circumstances that arose with regard to the superannuation of certain officers of Poor-law unions.

Dr. Lyons also supported the second reading.

Mr. Callan said he would join in the suggestion if it was proposed to examine in committee a few witnesses on each side.

Mr. Ewart said there was a desire in the north of Ireland for an improvement in the law in this respect, and the proposal that was made was very reasonable.

Mr. Biggar did not agree with the details of this Bill. The Local Government Board were asked to supersede the rights and interests of the ratepayers. The practical result of the Bill if it passed would be that the different officials would set the guardians, who were their paymasters, entirely at defiance, and would constantly appeal on all questions to the Local Government Board. He hoped this Bill would not pass this or any other session.

Mr. Fitzpatrick supported the second reading.

The motion for adjournment was negatived.

Mr. Callan hoped the hon. gentleman would have no objection that a few witnesses should be examined on both sides to test the merits of the Bill.

Mr. Gladstone said that, so far as he was personally concerned, he would have no objection whatever to that course being taken.

The Bill was then read a second time and referred to a select committee.

It will be observed from the foregoing epitome of the debate that the prevailing objection to the Bill was jealousy of the Irish Local Government Board, and that its chief opponents are the Irish irreconcilables. We do not at all regret that it has been referred to a select committee, if, in that reference, three considerations be observed—*First*. That the committee shall sit at once, so that the Bill shall not be delayed beyond the present session. *Secondly*. That gentlemen willing to take a fair view of the subject in the interest of the public and the officers of unions shall have their places

on the committee, and that it shall not be composed exclusively of the Parliamentary representatives of low-class guardians, few of whom could be trusted to treat their officers with decency, not to say generosity. *Thirdly.* That the *viso voce* testimony of a few well-informed witnesses be taken before the committee in order that the facts may be presented briefly and with more force than they could have if committed to paper.

We are fully confident that if the select committee will hear dispassionately the case for Irish Poor-law medical superannuation they must and will recognise the justice of the case on behalf of the medical officers; but we would greatly apprehend that, if a decision were given by them on the faith of written statements which could not be properly sifted, they might be disposed to yield to the desire for economy of the rates rather than the sense of what is just to public officers.

The select committee has not, at the date of our writing, been yet appointed; and though the proposed nominations have been placed on the notice paper of the House, it is likely that delay will occur in the appointment of the committee in consequence of the obstruction offered by Mr. Biggar and Mr. Daly. The gentlemen originally proposed by Mr. Herbert Gladstone were as follows:—The Attorney-General for Ireland, Messrs. Healy, Justin McCarthy, Meldon, Gibson, Fitzpatrick, Aylmer, Biggar, Sir Patrick O'Brien, Herbert Gladstone, Tottenham, Collins, and Mulholland. We hear that the Conservative leaders object, on principle, to the appointment of an exclusively Irish committee, while the Irish irreconcilables object to the nomination of any member who holds an English seat, even though he be an Irishman. Mr. H. Gladstone has therefore increased the committee to sixteen by the addition of Messrs. Green, Callan, and Findlater, while Mr. Biggar and Mr. Daly have put down notices to substitute other names for those of Mr. Meldon, Mr. Collins, and Capt. Aylmer.

This opposition has caused such delay in the appointment of the committee that it may be very difficult to pass the Bill this year, but we trust that not a day will be lost in setting the committee to work even with a view to legislation next session.

Messrs. Biggar and Findlater are known to be especially hostile to medical interests. The Irish Medical Association has already applied to be allowed to send a witness to the committee.

Notes on Current Topics.

Royal College of Physicians of London.

THE Royal College of Physicians seems to be fully determined to sustain the reputation it has gained of being, next to the General Medical Council, the most "do nothing" of all the medical institutions. On Thursday last a meeting of the Fellows was held at the College, when, after certain formal annual business had been transacted, attention was given to Dr. Sieveking's much-anticipated motion—"That the system of extensively advertising medical works in non-medical journals, and the custom of giving laudatory certificates of medicinal and other preparations, whether for publication or not, is

misleading to the public, derogatory to the dignity of the profession, and contrary to the traditions and resolutions of the Royal College of Physicians." This curious jumble of words was put in the form of a resolution without any attempt apparently to give it a more rational significance, or a more grammatical appearance; and cutting, so far as it can affect anything at all at the tenderest susceptibilities of more than one eminent Fellow present, it naturally underwent a good deal of modification. It would, of course, be extremely irreverent even to think anything that would "derogate" from the dignity of so august a body as the Royal College of Physicians; but the thought irresistibly suggests itself—"Quis custodiet custodes ipsos?" After much discussion the resolution was finally passed in a form which confers a plentiful measure of elasticity on it, and will tend to make it readily adapt itself to circumstances as they arise. This was effected by omitting the words "in non-medical journals," and adding after "other preparations" the words "and medical and surgical appliances." It is comforting to know that the assembled Fellows were honest enough to carry the mangled remnant of Dr. Sieveking's resolution "by a large majority;" but it is unpleasant, nevertheless, to reflect on the possibilities the future may present. We have from the first insisted on the utter futility of the College of Physicians acting in the childish fashion it has adopted. Who cares for its resolutions? Or even if a few upright and conscientious men do pay heed to them, they alone suffer the threatened evils, for a hundred others fearlessly transgress the resolutions for every one who abides by them. We venture to think the College of Physicians has rendered itself supremely ridiculous by this last performance; and that it very fittingly proceeded, after passing the resolution referred to, to elect as one of its prominent officers a gentleman who has persistently ignored the terms of a similar regulation in the past.

Irish Workhouse Administration before Parliament.

ON Wednesday last, Mr. Biggar gave notice of a series of questions imputing grave neglect of duty to the master of the Belfast Workhouse, who, it was alleged, had refused admission late at night to three persons bearing orders marked "urgent," and they were found by the police lying at the workhouse gate. It was stated that one of the three was an old man, seventy years of age, who was suffering from a severe attack of hæmorrhage; and another was an old woman of sixty-seven. It appeared that complaint had been made of previous cases, and also that the guardians had approved the conduct of the master; and Mr. Biggar intends to ask, if these allegations are true, what steps will be taken by the Local Government Board.

Mr. A. O'Connor also put upon the paper three questions with regard to the Carlow Workhouse. They refer mainly to the conduct of the chairman of the board of guardians, who is accused of having acted without the authority of the board in ordering additional works connected with the workhouse and infirmary; but the third question is as follows: "Whether Dr. Rawson, the medical officer, who also attends the soldiers stationed at

Carlow, has on several occasions introduced into the workhouse for treatment soldiers suffering from loathsome skin and other affections; and if so, whether the Chief Secretary intends to take any notice of the practice?"

The London Hospital.

IN our account of the recent prize-distribution ceremony at the London Hospital, we spoke of the awards being made to students and *practitioners*. This should have been students and *probationers*, the latter recipients being probation nurses who had attended classes regularly held for their instruction, and who had succeeded in obtaining the prizes offered for diligence in connection with their work. This feature is a good one, and is likely to be followed with advantage at other institutions besides the London. At the latter place, regular courses of lectures are delivered to the probationers by members of the medical and surgical staff, and with the most gratifying success.

Death of Professor F. M. Balfour.

THE greatest loss that English science could well sustain has been experienced in the death, last week, of Mr. Frank Maitland Balfour, Professor of Animal Morphology in the University of Cambridge. It is but a short while since we chronicled the fact of his election to the post thus rendered vacant, and which it is now well known was created with the express object of retaining Mr. Balfour at Cambridge. The circumstances surrounding his death are peculiarly mournful. He had gone for a few weeks' relaxation to Switzerland, and while climbing the Alps with a guide for companion, is supposed to have slipped and fallen; at any rate, his dead body and that of the guide have been discovered, but the particulars of the accident must of necessity for ever remain unknown. The late professor, though but thirty years of age, was the most distinguished graduate Cambridge has had since the time of Clifford, and in his own special field of embryology he was without a rival. The work he has already accomplished is a vast addition to our knowledge, and, thanks to his indefatigable industry, is embodied in a connected work which renders it accessible to every student. It will be impossible for Cambridge, even out of the rich store of distinguished scientists numbered among her own graduates, to replace the professor thus prematurely deceased, and the loss experienced also by the world of English science is one that cannot at present be made good. Mr. Balfour's work, however, is his best memorial, and in the influence exerted by it on future progress he will continuously, though dead in body, be alive and active in spirit to the unutterable gain of the science he so loved and served. The deceased naturalist was a Fellow of the Royal Society, Royal Medallist in 1881, M.A. and Fellow of Trinity College, Cambridge, LL.D. of Glasgow University, and President of the Cambridge Physiological Society. He was a younger brother of Mr. Arthur Balfour, M.P. for Hertford, and nephew of the Marquis of Salisbury.

Adulteration.

THE *Pharmaceutical Journal* reports that "In the London drug market last month some false *arnica* was offered for sale. Under the name of *coto bark*, a pale, aromatic, bitter, but not pungent, bark has been offered. It is probably the bark of a species of *Croton*, the flavour having a family likeness to that of *cascarilla*. Spurious saffron, of the kind described by Hanbury as being adulterated with carbonate of lime, is still extant in English commerce, two samples having recently been obtained in London."

We learn from the *Grocer* that a chop of tea, consisting of over a hundred half-chests, imported from Hong-Kong as "extra choicest Ningchow Congou," was sold publicly at from 6d. to 6½d. per lb., and has since been resold at a profit and distributed throughout the country. The top of each package consists of sound tea, but the remainder is composed of willow or other leaves mixed with some substance which has become putrid. The Customs authorities not only passed it, but refuse to return the duty which had been paid on the lots which the brokers took back from their customers.

The *Medical Times and Gazette*, referring to the yearly report of the English public analysts, says: "The adulteration of drugs is a serious matter, reflecting as it does on the character of a body of men who are presumed to hold a higher social position in virtue of their superior education than the petty tradesmen. It prevails in the rural districts to twice the extent that it does in towns, and in these again it is twice as general as in London. It does not appear whether the wholesale houses or the retailers are mostly to blame, but we greatly fear that if the truth were known it would be found that some of the former supply inferior articles to their country customers, presuming on the ignorance of the grocers and drapers, who, in small places, are at the same time retailers of drugs, and on their inability to test the quality of their wares by chemical or microscopical means."

The Report on Irish Lunatic Asylums.

MR. CORBET, last week, asked the Chief Secretary for Ireland when the report of the Inspectors of Lunatics on Irish Lunatic Asylums for the year ending 31st of March last would be presented to Parliament.—Mr. Trevelyan said: The Inspectors of Lunatics cannot fix any date for the presentation of their report. It is, however, in the hands of the printers, and the Inspectors hope to have it ready before the close of the session.

Mr. Thomson's Innominate Case.

AT the post-mortem examination of this case, which we reported in our last as having died on the 42nd day, it was found that the sinus from which the bleeding took place terminated in an ulcer, which involved the anterior wall of the junction of the innominate, carotid, and subclavian arteries. The innominate and carotid were filled with clot; the subclavian contained a clot occluding it to the extent of half an inch. The position of the ulcer was on the distal side of the ligature, the constricted portion of the innominate not being involved. The hæmorrhage had apparently taken place from the innominate, as there was a recent blood stain on the cardiac side of the clot. None

of the vessels were pervious to water forced in with a syringe. The aorta was atheromatous. Consolidation was proceeding satisfactorily in the tumour. Excluding the successful case of Dr. Smith, of New Orleans, this is the second longest survival on record; Graefe's case having reached the sixty-seventh day, and Cooper's the thirty-fourth.

Unqualified Assistants.—Conviction for Homicide.

A STUDENT, who had been assistant to a practitioner in Dumfries, was recently charged with culpable homicide. When in attendance on a woman, he administered to her, by hypodermic injection, from twelve to fifteen minims of a solution of morphia, whereby she was immediately reduced to a state of insensibility, and died about four hours afterwards. At the first diet of the court, the accused pleaded not guilty, but subsequently he stated his intention of pleading guilty. The sheriff imposed a fine of £20, or alternatively a month's imprisonment.

A NOVEL and important decision was given in a case tried on Tuesday, July 11th, at the Lambeth Police Court, before Mr. Chance. Mr. C. F. Groom, M.R.C.S. Eng., was summoned at the instance of the Medical Alliance Association for wilfully making a false certificate, under or for the purposes of the Births and Deaths Registration Act, 1874, concerning the death of a child named Mary Louise Sparks, on the 28th June, 1882. It was proved at the hearing that the defendant had seen the child once, and had made up a bottle of medicine for it. Mr. Chance, however, held that one solitary attendance did not amount to that degree of investigation and attendance of the patient's case which would justify the defendant in giving the usual form of death-certificate under or for the purposes of the Act, which he had done. He therefore convicted him of the offence charged, and fined him £2 and £2 2s. costs. This is, we believe, the first judicial definition of what amounts to an "attendance" under or for the purposes of the Registration of Deaths Act sufficient to justify the medical practitioner in charge in giving the usual form of certificate of death; and it deserves serious consideration.

The Doctor's Brougham.

It will interest many of our readers to learn that there is every probability that the Prime Minister, in deference to the generally-expressed dissatisfaction at the proposed increase of the tax on carriages, will abandon this item in the year's revenue. We trust our optimist views on this subject will not be disappointed, and that the doctor's vehicle, which is as necessary to the proper carrying on of his profession, especially in country practice, as is any other item of his armamentarium, will not be loaded with the additional cost of two guineas per annum.

THE Irish newspapers report the death, last week, near Kingscourt, in the co. Cavan, of an old woman named Melady, at the mature age of 105; she retained her faculties up to her death; her eldest great grandchild is 24 years of age.

The Chelsea Hospital for Women.

THE self-help principle has been introduced into this hospital, both in the in and out-patient departments, ever since its foundation, eleven years ago, during which time £3,400 has been contributed by the small payments of those patients who have been unprovided with a subscriber's free letter. This averages 2s. 6d. from every in and out-patient treated. From the medical report presented at the annual meeting on Saturday last it appears that in-patients have been received from Biarritz, Queensland, the Cape of Good Hope, Buenos Ayres, &c. In view of removal to the new hospital in the Fulham Road, the following additions have been made to the medical staff:—Physicians: John James, M.B., F.R.C.S.; A. W. Edie, M.D., F.R.C.P.; and Assistant-Physicians, Fancourt Barnes, M.D., M.Ch., and John Phillips, B.A., M.B. In appealing for increased monetary assistance the treasurer said that, although the financial results of the year had been very satisfactory, there was urgent need of contributions to pay off a mortgage of £5,000, and that £7,739 invested in the Funds had to be sold out to pay the instalments due upon the contracts for the new hospital, which it is expected will be ready for the opening ceremony early next year.

Dissolution of a Board of Guardians.

IT is truly gratifying to witness the display of a little unwonted *fortiter in re* in the proceedings of the Irish Local Government Board. We are, therefore, pleased to observe that the Carrick-on-Suir Board of Guardians have been dissolved by the Local Government Board for neglect of duty. It appears that, as a measure of retaliation for the refusal of the chairman to put a political resolution, the majority of the guardians adjourned the meetings four times in succession, leaving a large amount of urgent ordinary business unattended to. *Oh, si sic omnia!* If the Local Government Board would only erase a dozen or two of the conclaves of village politicians who misuse the Poor Law of Ireland what a blessed riddance we should have to be thankful for!

Iodoform in Diabetes.

PROFESSOR MOLESCHOTT, of Rome, has published a series of articles in the last numbers of the *Wien. Med. Wochens.* on the use of iodoform in the treatment of diabetes mellitus. For some months together he kept a series of five patients suffering from this disease under treatment by the drug, and from the results obtained came to the conclusion that iodoform was a drug that promised much in this affection, inasmuch as under its employment for a few days or weeks the sugar disappeared. In those cases that were not cured the sugar reappeared on the discontinuance of the employment of the iodoform, to disappear again when its use was resumed in increasing doses. It further promised much as the improvement set in even when the use of starchy foods was not limited, and even when the patient had to contend with exciting cares and excessive labour. A cure was effected in one case that had withstood the action of salicylate of soda. He recommends iodoform gr. xv., extr. lactuc. sat. gr. xv., "cumarin" 1-15, to be made into twenty pills,

of which one may be taken from twice to eight times a day.

[The form recommended by Anthofer, and published in this journal, page 345, 1882, vol. i., would be a suitable form for administration.]

Accidents in Lunatic Asylums.

A PATIENT in the Waterford District Asylum died recently under circumstances which necessitated an inquest. She is stated to have been restless and unmanageable, and when being brought by the nurse to her room, to have fallen and cut her face, and becoming suddenly ill, to have died within forty minutes. The resident medical superintendent is reported to have expressed himself at the inquest as "quite satisfied that no violence was used to the deceased," but he could "not say without post-mortem examination whether she fell through heart disease or sudden weakness," but he "thought she died from nervous shock, caused by the fall." Perhaps she did, but why was not the cause of death thoroughly sifted? This is just one of those cases which makes us jealous for the presence of other eyes within the asylum besides those of the administrative officers. It is, of course impossible to prevent occasional accidents in large institutions of this sort, and we do not for a moment hold the officers answerable for such misadventures, but we insist that, when they occur, they should be thoroughly investigated, and it does not satisfy us that lunatic patients should die within a few minutes of a personal injury, and that the public should know no more about it than the report of a nurse and the guess-work diagnosis of a medical officer.

M. FAUVEL relates an instance in which he found a bullet in the larynx ten years after it had entered the head.

PROFESSOR NOTHNAGEL is now definitely named Professor of Special Pathology, Therapeutics, and Clinical Medicine in the University of Vienna.

THE Bradshawe Lecture will be delivered this year by Dr. Long Fox, on Friday, August 18th. The subject will be "The Influence of the Sympathetic System on Disease."

SEVENTEEN anti-vaccinators were last week fined 20s. each and costs, at the Eastbourne Police Court, for neglecting to have their children vaccinated. A case for appeal was granted.

ON the 22nd July a solemn leave-taking took place in honour of the departure of Langenbeck from Berlin, in which students from all the faculties, teachers, and other admirers of the great surgeon took part.

ACCORDING to the proposed New Regulations of the Lord Chamberlain, a doctor is required to be in every theatre during a performance. When a piece runs for, say five hundred nights, as many do, his occupation will become slightly monotonous.

IN addition to the medical staff for Egypt, given in our last, Surgeon-Major Frederick Hume-Spry, M.D., of the 2nd Life Guards, has been selected to take medical charge of the Household Cavalry Brigade there.

COMPLAINTS are constantly made of some of the deodorisers used in several large cities; these are so strong and disagreeable as to be positively sickening. Some correspondents preferring the chance of infection to the disinfectants.

DERBY gave the extraordinary low death-rate last week of only 8 per 1,000 of its population (83,587). The highest rate reached was at Preston, where the mortality was 30 per 1,000 in a population of 97,656; the excess being chiefly attributable to diarrhoea.

THE Japanese Government has lately drafted new regulations for marriages. According to these, no man in the empire will henceforth be permitted to marry before arriving at the age of twenty. Women, however, are to be privileged to marry at eighteen.

MORE than half a ton of strawberries and other fruit was distributed to the hospitals in the metropolis by the South London Committee of the Hospital Saturday Fund last week. The fruit was presented by the growers and carried free of charge by the South-Eastern Railway Company.

THE attempt made by certain guardians to oust Dr. Pullin from his position as medical officer of the Honiton Union has failed, the result of inquiry being to relieve Dr. Pullin from blame, while recognising that he should have been more alert to obey the call made on him to visit a patient.

LADY CORMACK, widow of the late Sir John Rose Cormack, has just died at her residence in Paris, having survived her husband little more than two months. She had long been in impaired health, having suffered much during the siege of Paris in 1870, during which she remained in that city with Sir John Rose Cormack.

THE heat is so intense at New York and other cities in United States, that numerous deaths from sunstroke are daily reported. The epidemic of diphtheria has happily been overcome in New York, and deaths from diseases of the zymotic class are now merely nominal. Typhoid is still prevalent in Paris, and diarrhoea excessively fatal in Berlin.

THE appointment of Dr. Finny to the King's Professorship of Medicine in the School of Physic attached to Trinity College, Dublin, and his consequent connection with Sir Patrick Dun's Hospital as Clinical Physician, caused him to vacate his office as Physician to the City of Dublin Hospital. To that position Dr. George Duffey, Lecturer on Materia Medica and Therapeutics in the Carmichael School, has been elected, and he consequently vacates the Physiciancy of Mercer's Hospital, which he has held for some years.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

UNIVERSITY OF GLASGOW.—The graduation in medicine, and the distribution of medals and certificates of merit in connection with the medical classes at the University, took place on the 27th ult., in the Lower Hall of the Museum. The Very Rev. Principal Caird presided, and Prof. Charteris, M.D., delivered the valedictory address, in which he said he wished to speak some plain practical words to those who had just completed their studies as to the course they were now to pursue. Some, he said, might be in a position to make a foreign tour, to look forward to spending a year or two at the most noteworthy Continental schools, previous to settling at home. To this there could be no possible objection, for they would meet there in familiar intercourse, in the ward or in the laboratory, many men whose names were known to them by text-book or lecture. Such an intercourse and such a tuition must expand their mind and augment their scientific training. Moreover, it facilitated their acquisition of a modern language, and that in this cosmopolitan age was no slight advantage. He questioned, however, if recent subserviency to German researches in medical matters had not, like a kind of fetish worship, tended to lower our national character by weakening our native powers of original work and habits of sturdy independence both in the realms of thought and practice. In no other practical pursuit did we find the Anglo-Saxons rush to other lands for knowledge as though they were unable to find it in their own. Our proud position had ever been in the first rank. Granted that the Germans were the most patient of investigators, the most fertile of theorists, the most encyclopedic of recorders, it must yet be added that they were the most unspractical of men. From personal experience, he could unhesitatingly say that the hospitals in which those before him had been trained were better than theirs. They were better ventilated, better drained, more cleanly kept, less overcrowded; and who could doubt the patients were better treated, and more with a wish to preserve life than with a curious desire to speculate on the cause of death? One thing they could, however, learn from the Germans, namely, each one to do work for his own hand in his own chosen department. To those who found it necessary at once to begin practice, the speaker proceeded to give various practical advices, concluding by conveying the heartiest wish of the Professors for the future welfare of their students.

UNIVERSITY OF EDINBURGH.—PORTRAIT OF DAVID HUME.—At a meeting of the Senatus Academicus, on Friday last, a copy of an original and interesting portrait of David Hume was presented to the University by Lady Abercromby, through Professor Campbell Fraser. The original picture belongs to the Camperdown family, and is now at Weston House, Warwickshire. This finely-executed copy has been taken by Lady Abercromby herself, for presentation to the University of Edinburgh, with the desire that this memorial, the work of one of his own countrywomen, should commemorate the great Scottish historian and philosopher, in the city of his birth, and in his own University.

CHAIR OF SURGERY IN THE UNIVERSITY OF EDINBURGH.—At a meeting of the Senatus Academicus, on Friday last, July 28th, John Chiene, M.D., F.R.S.E., presented his commission, and was duly inducted as Professor of Surgery in the University.

EDINBURGH DENTAL HOSPITAL AND SCHOOL.—At a meeting of the directors of this institution, held last week, the

Dean, in bringing up his half-yearly statement, said that with regard to the students who were attending the University medical classes from the Dental Hospital, he had a gratifying report to make. During the winter session Mr. James Graham Munro obtained first prize in physiology, while Mr. David Dewar Hepburn was second prizeman in anatomy. For the summer session, in the junior division of the practical anatomy class, although medical students were in the proportion of five to one of the dental students, three out of the four honours in the class were gained by dental students—James Johnston taking first place, James Graham Munro second, and John T. S. Hughes fourth place. In the chemistry classes at Minto House, Messrs. Hughes and Munro received each 92 per cent. of marks, and Mr. Johnston 89 per cent. At the same meeting Dr. Joseph Bell was elected honorary consulting surgeon to the dispensary, in room of the late Professor Spence. The chairman afterwards presented the prizes offered by the Dean for general excellence in hospital work during the summer session, Mr. Joseph Smithson Thomson being awarded the prize in the senior division, and Mr. J. G. Munro the prize in the junior division. In congratulating the students on the nature of the report, Dr. Sandford said it was gratifying to know that the recent Act of Parliament had done much to raise the status of the gentlemen who belonged to the dental profession to a higher level than hitherto, and he was sure that the sense which their instructors had of the benefit of the Act of Incorporation would tend greatly to raise in the students' own estimation the work to which they were going to devote themselves.

Literature.

BILLROTH'S CLINICAL SURGERY AND REPORTS OF SURGICAL PRACTICE. (a)

WE hail with pleasure the appearance of this work, under the auspices of the New Sydenham Society, the translator being Mr. C. T. Dent, F.R.C.S. The name of Billroth is sufficient to recommend it to the notice of the profession. The opportunities of this distinguished surgeon have been very great, and he has fully availed himself of them, and the volume before us is to a certain extent the result of his labours in practical surgery.

The work is an abridged translation of four volumes of hospital reports, and relates to Professor Billroth's surgical experiences between the years 1860 and 1876. The original German work in its entirety comprised some eighteen hundred pages, and to reduce it within the prescribed limits of the Sydenham Society volumes has been a difficulty of no small importance to the translator. However, we can congratulate him on the manner in which he has accomplished his task. In order to curtail, in some instances certain parts had to be sacrificed as a matter of course. A considerable amount of rearrangement was also necessary; but the general plan of the work appears to have been adhered to.

The Reports are collected from two sources: from the year 1860 to 1867 the field of Billroth's labours was the Zurich Hospital; and from 1868 to 1876 they are collected from the General Hospital, Vienna, at which institution Billroth is at present an ardent worker.

The translator divides these reports into twenty-two chapters. Chapter I. treats on the important subject of "Antiseptic Treatment of Wounds and Anæsthetics."

Billroth states: "In 1875 I first began to employ the antiseptic method regularly. In 1877 my assistant, Dr. Wölfler, journeyed to England, France, and Germany, and brought

(a) "Clinical Surgery: Extracts from the Reports of Surgical Practice between the Years 1860 and 1876." By Dr. Th. Billroth, Professor of Surgery in Vienna. Translated from the original, and edited with Annotations, by C. T. Dent, F.R.C.S., Assistant Surgeon to St. George's Hospital; Surgeon to the Belgrave Hospital for Children. With nine lithographs and twenty-nine woodcuts. The New Sydenham Society. London. 1881.

back with him the most recent modifications of the method, whereupon we began afresh with our antiseptic treatment." After speaking very fully on this subject he implies that the method has not been entirely successful in every case in his hands, and says: "Without venturing to assert that I have come to any final conclusion on the subject of the advantages of antiseptic dressings over other methods of treating wounds, I think I may say that practically it is an admirable method, and I shall always recommend it as safe and reliable until some better mode of treatment has been devised." When speaking on the subject of anæsthetics, he remarks: "At the end of the year 1878 I had had a quarter of a century's experience in operation, more than six years as assistant, and the rest of the time in the charge of my own clinic. During this period I had seen chloroform administered some 6,000 times, with 2 cases of death. Up to the end of 1870 I always employed chloroform alone as an anæsthetic; since then I have used a mixture consisting of three parts of chloroform, one of sulphuric ether, and one of alcohol. With this anæsthetic I am perfectly well satisfied, and have not seen any asphyxia or syncope result from its use. The mixture seems to me merely of service in diluting the chloroform."

On all the surgical subjects treated throughout the volume the author gives a vast amount of practical information, rendering the book a useful reference manual for young practitioners. It is illustrated by twenty-nine well-finished woodcuts, besides having some excellent lithographed plates with descriptions at end of work. We strongly recommend the book for perusal, feeling sure that few will read it without deriving information; besides, it constitutes one more valuable addition to the long list of useful works issued by the New Sydenham Society.

Correspondence.

THE COMPULSORY NOTIFICATION OF DISEASES BY MEDICAL MEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A few days since I received a letter from the Town Clerk informing me that he would send blank copies of a notice to be forwarded by me to the medical officer of health of all infectious diseases that came under my notice, and accordingly I received the enclosed and a book containing twenty-four blank notices with a halfpenny stamp on back, and directed to "The Medical Officer of Health." I hold no office, post, or appointment of any kind, am under no obligation to any one here, and should not like to take the office of a detective, for by furnishing information, to the prejudice and annoyance of any person who might wish to have my professional advice, I should be acting in that capacity in their houses, without even the mercenary excuse of being paid for such dirty work. I am on friendly terms with the Town Clerk, and entertain a high opinion and much respect for the medical officer of health, and am sadly at a loss to know what is the proper course to adopt towards these gentlemen. If no law compel me, I shall refuse to comply with this regulation, although I consider there should be some law to compel the patient's friends or the occupier of the house to supply information which may lead to the suppression of such infection. The notice, I may add, would lead one to suppose that cases of venereal, itch, and the like are included.

Yours faithfully,
M.D.

[Our correspondent should first ascertain if a local Act has been obtained for his district. If it has, the iniquity has been perpetrated, and he must supply information of even slight cases, under penalty. If such Act does not exist, he may put the notices in his waste basket.—ED.]

Gobelities.

FLUID EXTRACTS OF CINCHONA.

THAT fashion swells immensely the already over-burdened vocabulary of our *Materia Medica* there can be but little dispute. Some of the remedies brought forward are but short-lived, through obvious failure when tested with the experience of daily practice. Others succeed, and are at once classed with our reliable armamentaria. Cinchona

bark, opium, and such well-known drugs and their alkaloids, are as much relied upon as they were a quarter of a century since, and they will continue to hold their own so long as the drugs themselves are not found in a deteriorated condition, and their respective alkaloids are prepared in a state of commercial purity.

We notice from time to time in publications touching on pharmacy that no secret is made by practical men that the flat yellow bark (*Calisaya*) that we were accustomed to see in our student's days is now a thing of the past; in short, that all bark of such character is absolutely worthless in its quinine assay.

This might be viewed seriously were it not that we are aware that the British Government, as well as coffee planters and others, have not only been for some time actively engaged, but have actually succeeded, in producing in British India a bark containing large proportions of alkaloid, the bark itself being admirably suited for the production of a fluid extract, which may with advantage be exhibited in all cases where the use of Cinchona is indicated. For some time we have been using one of these extracts (Umney's Fluid Extract of Cinchona), both in hospital and private practice, with the most satisfactory results. It is, we believe, made from the variety known as *Cinchona Succirubra*, the bark of which contains not only a considerable portion of Quina, but large quantities of Cinchonidine and other alkaloids.

KANDOLT'S APERIENT TAMARIND LOZENGES.

THERE is, of course, nothing new in the use of the tamarind fruit as an aperient. Its action is so certain and its taste so agreeable, that the wonder is resort is not more commonly had thereto by persons of constipated habit. Probably the principal objection is to the form in which it is imported—in large jars of seven or eight pounds' weight, which are formidable, and withal inconvenient. A German chemist (Kandolt, of Gotha) has sought to remove this objection by compressing the tamarind, minus its stringy accompaniments, into the form of lozenges, one of which is a dose for an adult, and a half or a quarter for children, according to age and circumstances. In this form a mild, safe, and agreeable laxative is always at hand, which will be highly appreciated by those to whom mineral waters, or patent medicines of an unknown composition are an objection.

PORTABLE BOX FOR TESTING ARSENIC.

MESSRS. GRIFFIN and SONS, of Garrick Street, London, have submitted to us a neat portable box of very simple apparatus for the purpose of testing arsenical wall-papers and arsenic in domestic fabrics generally. We have already intimated that the Society of Arts, by the aid of a committee have undertaken to furnish a standard and infallible test apparatus for the detection of the minutest quantities of arsenic; but to apply a test with scientific accuracy it would require an amount of chemical knowledge and skill, as well as apparatus, which few persons would be likely to possess. To enable the public to protect itself, and at a cost which shall be trifling, against the dangers arising from poisonous materials so much employed at present, it became necessary to provide not only a cheap set of apparatus, but such as can be readily applied by almost any one who has seen an experiment performed in a lecture-room, or, at all events, who may be supposed to possess no practical knowledge of chemistry. This, then, is what Messrs. Griffin and Sons have done. In a small box, four inches square, and at the cost of a few shillings, they have managed to pack all the necessary apparatus, tests and test tubes, by means of which any one can ascertain whether the article purchased is free from arsenic. Should this convenient and useful apparatus become generally adopted, the use of arsenical colours will of necessity be abandoned by manufacturers.

BRAND AND CO.'S ESSENCE OF MALT.

MESSRS. BRAND and Co. now prepare a concentrated essence of pure malt, which we have recently had under trial with excellent results. In one case—that of a lady troubled with long-standing inability to retain food for any length of time on the stomach—the malt essence has been found of the greatest use, and has so far succeeded in overcoming the difficulty that the process of digestion is now almost always completed. It contains an active body allied to diastase, on which much of its virtue probably depends, and it is certainly of the

almost value to persons of weak digestive power. It is pleasant to take, and easily mixes with water, sherry, &c.

The essence is prepared by a special process patented by Messrs. Dence and Mason (Brand & Co.), and the claims made on its behalf are thoroughly substantiated by experience in its use.

OLD BOTTLED WATER.

The Medals have recently been issued by the jurors of the International Balneological Exhibition at Frankfort-on-the-Maine, where specimens of all the famous mineral waters of Europe were exhibited. The prize medal for English mineral waters was awarded to Messrs. W. and J. Burrow, of Malvern, whose exhibit was one of the most remarkable in the Exhibition, being specimens of the Malvern Waters bottled by them ten years ago. Notwithstanding the length of time the waters had been in bottle, they were found on opening as fresh and pure as when first drawn from the Malvern springs. No water containing organic matter would keep good for so long a time. This is a convincing test of purity.

PASS LIST.

Royal College of Physicians of London.—The following gentlemen were admitted Fellows of this College on Thursday, July 27th:—

Blanc, Henry, M.D. Montpeller, Bombay
Grant, James Alexander, M.D. Montreal, Ottawa.

The following candidates having passed the required examinations, were admitted Members of this College on Thursday, July 27th:—

Grabham, Geo. W., M.D. Lond.
Herringham, W. F., M.B.
Jenior, Charles Moore
Jones, A. Henry, M.D. Lond.

MacLagan, T. John, M.D. Edin.
Richardson, Gilbert, M.D. Dub.
Rouh, A. J. McC., M.S. Lond.
Shaw, John, M.D. Lond.

The following were admitted Licentiates on Thursday, July 27th:—

Alpin, William G. Patrick
Bamford, Charles Robert

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on July 20th:—

Birch, Henry Priestley
Caryon, Edward T. wbody
Fenner, Robert Nathaniel
Knight, Frederick
Russell, Robert Hamilton

Sheppard, William John
Thring, Edward Thomas
Tresidder, Edward Stanley
Williams, Edward Richard
Wilson, Mervyn Seppings.

The following were admitted Members on July 21st:—

Back, Herbert Hatfield
Barber, Alfred
Berry, James
Blagg, Arthur Frederick
Boiler, Frederick James
Frost, George

Howell, James Bromley
Marsh, Nicholas Percy
Maude, Arthur
Nicolson, Robert Howard
Skipper, Edward
Viney, J. Ernest, M.B. Cantab.

The following were admitted Members on July 24th:—

Anderson, Alfred Jasper
Carr, Thomas
Clarke, Louis Bennett
Davies W. T. Frederick
Eastes, Frederick
Elgood, Charles Reginald
Gibson, John Hutchinson

Hern, William Ashburton
Jacob, Arthur Howard
Jones, Isaiah Henry
Quick, Frank
Toller, C. W. Edward, L.R.C.P.
Lond.
White, Ernest Alfred.

The following were admitted Members on July 25th:—

Banatvala, H. E., L.R.C.P.
(amphib.) Samuel George
Gordon, Edward, L.S.A.
Gracie, Charles Eatten
Freeborn, J. C. Richard

Harratt, Henry
Kelly, Charles Augustus
Lilley, Frederick John
Spang, William
Thomas, John Lloyd, L.S.A.

The following were admitted Members on July 26th:—

Benjafield, Wm. B., M.B. Edin.
Beverley, John Metcalf, L.S.A.
Fowler, Charles Owen, L.S.A.
Massey, Henry Massey

Poocock, R. Knox, M.B. Edin.
Pryce, Thos. Davies
Wilson, Reginald William
Wilcocks, Arthur Durant
Wilcox, Ernest, M.B. Edin.

Royal College of Surgeons in Ireland.—At the Examination in General Education held on the 19th and 21st July, the following gentlemen were adjudged certificates of qualification, the names in the first and second classes being arranged in order of merit:—

First Class.—Victor Fenton; Ambrose J. Birmingham and Thomas Carr, equal; John C. O'Sullivan; Joseph Nalley; John H. Jones and Henry Powell, equal; David Dubia and William Kerr, equal; Michael T. Casey. *Second Class.*—Alfred C. Burges and Frederick A. Malcolmson, equal; Francis H. Hill and William T. Steele, equal; Joseph Casey; Thomas G. W. Carpendale; Richard J. Dodd, James F. Hanrahan, John R. Hinkson, Thomas McEllistrem, Frederick de J. Patterson, Charles A. Wickham, and Edward Yates, equal; Louis Burgoyne and Richard W. Dillon, equal; Bartley H. Hopkins, Charles McDonnell, and Henry L. McDonnell, equal. *Unclassed.*—James Boyan, James Butler, Valentine Carney, Robert Cody, Edward A. Cooke, Joseph Costelloe, St. Leger J. Edmundson, John P. Friel, William Greene, John C. Hamilton, William P. Harding, Waltham H. Hilliard, John Lagan, Francis J. Martin, Michael H. McGann, John Morrison, James K. Mortell, Thomas Rossiter, John A. Ryan, William J. Ryan, Patrick J. Sheedy, and Edward H. Wheeler. Twenty-five were stopped.

The following have passed the first half of their examinations for the Letters Testimonial of the College, viz.:—

Edward L. Abern, Henry T. Baylor, Joseph Coffey, George P. Cope, Walter W. S. Corry, William P. Delahunt, Patrick J. Dillon, Thomas J. Dillon, Sinclair Finlay, George B. Heffernan, Joseph P. Kelly, Wm. Love, Mathew Macnamara, Michael J. McCavan, Richard Murphy, Patrick H. Murphy, Joseph Purdon, Robert U. Russell, James D. Ryan, John C. Sody, Thomas W. Sprowie, and William H. Waterfield. Forty-nine were stopped.

University of Glasgow.—The following candidates have obtained the degree of Doctor of Medicine (M.D.) of this University:—

Adam, Thomas Bate, M.B.
Guthrie, Thomas Orr, M.B.
Halket, George, M.B.
Orr, Alex. Brodie Seton, M.B.
Pollack, Charles Fredk., M.B.
Rankin, Guthrie, M.B.

Taylor, David, M.B.

Doctor of Medicine and Master in Surgery (M.D. and C.M.).
Smith, Frederick Augustus A., England.

Bachelors of Medicine and Masters in Surgery (M.B. and C.M.).

Beith, Robert, Scotland
Bell, Andrew, L., do.
Brown, John, do.
Buchanan John, do.
Campbell, Dugald, do.
Carroll, Joseph, do.
Caruthers, John, do.
Carrwell, Fergus, do.
Clerk, Norman M.L., do.
Crawford, Robert, do.
Donald, David, do.
Dougal, Wm. T., do.
Dunlop, John, do.
Dunlop, Thomas, do.
Dunlop, Thomas G., do.
Dunn, Thomas S., do.
Fotheringham, John, do.
Galbraith, Alex., do.
Gallie, Chas. Pinel, Jersey
Gardner, David, Scotland
Gardner, James, do.
Geddes, Robt. J., M.A., do.
Gillies, Hugh C., do.
Goff, John, do.
Grime, Thos. J., England
Haddow, George, Scotland
Haworth, Fred. G., England
Henderson, John C., Ireland
Henderson, J. H., Scotland
Hodgson, Isaac C., England
Hood, Alex. Jarvis, Scotland
Horn, Robert, do.
Howells, Wm., Wales
Jardine, James, Scotland
Johnston, John, do.
King, James, England
Lawrie, Wm. J., Scotland

Love, Duncan, do.
Lowe, Alex., Scotland
Marshall, John N., do.
Martin, Matthew, do.
Meighan, Alex., do.
Miller, James, do.
Miller, John M., do.
Mure, Richd., do.
Morton, Alex. Y., do.
Macdonald, J. D., Scotland
Macdonald, Thos. F., do.
Macintyre, John, do.
MacKay, John Y., do.
McLean, Peter, do.
MacLennan, Norman M., do.
Macleod, Herbert A., India
MacMillan, John, Scotland
McNish, James, do.
McPhun, John F., do.
Oastler, James, do.
Pattullo, Wm., do.
Ramsay, Andw. M., do.
Rennie, James S., do.
Robinson, Wm. T., England
Sandel, Anundo L., India
Semple, Andrew, Scotland
Simpeon, John P., do.
Sinclair, Dugald, do.
Sinclair, John, do.
Smith, Patrick A., do.
Tennent, Joseph T., do.
Thomson, R. S. B.Sc., England
Turner, Andrew D., Samoa
Waddell, Wm., Scotland
Webb, Henry P., England
Wilson, James L., Scotland
Wilson, Wm. M., do.

The following gentlemen were named as entitled to Honours, to High Commendation, and to Commendation, on account of distinguished merit at the various examinations for the degrees of M.B. and C.M.:—*I. Honours.*—Beith, Robert. *II. High Commendation.*—Love, Duncan; Thomson, Robert, S., B.Sc. *III. Commendation.*—Bell, Andrew J., Carwell, Fergus, Dougal, Wm. T., Geddes, Robert J., M.A., Marshall, John N., Macintyre, John, MacKay, John Y., MacMillan, John, Oastler, James, Pattullo, William, Ramsay, Andrew M., Webb, Henry P.

* Mr. Beith gained the Brunton Memorial Prize, awarded to the most distinguished Graduate in Medicine of the year (1882).

Master of Arts (M.A.), with First-Class Honours in Classics.—Dodds, James M., M.A., Scotland. *Certificate in Engineering Science.*—Carson, Alexander, C.E., Scotland.

South London School of Pharmacy.—The following prizes were awarded last week at this School:—Senior Chemistry: Mr. Caldecot (medal). Junior Chemistry: Mr. T. B. Tyson (medal). Botany: Miss Mitten (medal). Materia Medica: Mr. F. Ransome (medal). Practical Dispensing and Pharmacy: Mr. C. L. Dillon (medal). Senior Chemistry: Mr. Bain (certificate). Junior Chemistry: Mr. F. Ransome

(certificate). Botany: Mr. C. E. Hartson (certificate). Materia Medica: Mr. C. E. Hartson (certificate). Practical Dispensing and Pharmacy: Mr. T. B. Tyson (certificate). Certificates of Merit were also awarded to Messrs. Dowdeswell, Dillon, Hornby, Schofield, Thomas, and Thistleton.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. J. SHUTER.—Communication received while we were at press; reference will be made thereto in our next.

DR. PEARSON AND DR. DRYSDALE.—If possible in our next.

DR. SUNTER is thanked for his note. The error which was so palpable, was made so long since that it is hardly worth calling attention to at the present time. The quotation from *Punch* is apropos and highly amusing on the subject of baronetries.

DR. WOLF.—Dr. Jacob's lectures have been unavoidably held over. We hope to commence their publication in our next issue.

MR. DAVENPORT.—The paragraph quoted should read thus:—"For in one case only could you obtain anything approaching this strength." The word *no* instead of *one* was an obvious misprint.

DR. A. C.—Registration confers no privileges except that of being able to recover fees in a County Court. For all other purposes your diploma offers more valuable testimony than an entry in the Register, and candidly, we do not think you will obtain an adequate return for the £5 you will be required to disburse. There is no charge for insertion in the Directory.

MR. WILLIAMS.—St. George's was the hospital referred to. The information was quite correct, as you will have discovered. In any future communication please be good enough to remember the rules under which letters are received.

CANNINE.—Mr. Hill's work on the "Diseases of Dogs" is a valuable treatise, and will give you all the information you require. Dr. Carpenter's work on "The Microscope" (J. and A. Churchill's) is the best book we can recommend on the subject. There has been a recent edition.

SURGICUS asks if we think he might presume to write to the authors of certain papers concerning the subject of an operation in which he is interested, and which has been written on by several surgeons. We do not think any gentleman would feel otherwise than gladly willing to afford any assistance or explanation in his power to a brother inquirer, and we would recommend "Surgicus" by all means to write as suggested.

RAIN WATER.—The water collected from housetops is usually contaminated to a greater or less extent. The best roofing is, undoubtedly, good slate. You should carefully examine all water employed for chemical purposes, and reject what is not found to be absolutely pure. Distilled water is the only reliable liquid.

BLUE SPECTACLES FOR THE ARMY.—The Government have ordered 25,000 blue spectacles or "goggles" for the use of the army in Egypt. The contract price is 2jd. a pair. We doubt if the manufacturer will be able to retire this year from business on the profit.

DR. SMITHSON.—A case in point occurred last week at Wolverhampton at the meeting of the board of guardians, of which town a letter was read from the Local Government Board, stating that a vaccination certificate could only be given by a qualified practitioner who had personally vaccinated the child. This decision effectually settles the matter.

DR. J. E. B. will receive a private note in a few days, when the necessary inquiries have been made.

MR. WOOD (Edinburgh).—You will find the new edition of Harris and Power's "Handbook for the Physiological Laboratory" of the greatest assistance in the prosecution of your studies.

MR. A. WRIGHT.—The law requires that the actual attendant on the case shall certify the death, and no one can, except under severe penalties, act for another in the matter. It thus renders the whole subject one of considerable difficulty, since there is absolutely no escape from the obligations insisted on in the Act. Whatever the result, it is a subject of vital interest to the profession.

FRANCIS A.—We do not, as a rule, pay any heed to such reports. This one, however, is beyond doubt founded on fact, and we have no option left to us in the matter. If you will send the papers we will hand them over to a gentleman who has made the subject his own, and by whom they will be fully considered.

A DISGUSTED ONE.—A correspondent signing thus wishes our opinion, in "Notices to Correspondents," on the Compulsory Notification of Diseases Act as it affects him. He says: "I have as patients two children (daughters of a butcher doing a very extensive business) down with scarlatina. If I notify the fact to the medical officer of health, the precautions he must necessarily take under the Act will cause the matter to be noised about, and no one will go near the place for months. The tradesman will thus be ruined in business, and the rest of the public will decline to call me in when medical aid is required because I had turned 'informer.' The children are isolated; there is no fear of infection; but the law says I must notify, which I have not as yet done. Please advise me."

[Our correspondent will find our reply at the foot of another letter in the Correspondence column. Our opinion of the injustice of this Act receives daily confirmation.—Ed.]

DECLARATIONS BEFORE MAGISTRATES.—"Myocotis" says: I am a medical practitioner and J.P. for the county, and on a few occasions when signing "declaration forms," the declarants, who happened to be residents in England, tendered a fee of 2s. 6d., which, to their surprise, I declined. They said it was the invariable custom in England for the magistrate to get 2s. 6d. for such services. Will you be good enough to tell me in your columns for correspondents if such be the rule, as I was under the impression that the distinction was purely honorary, and debarred the recipient from taking any emolument for magisterial services?

[Page 523, Humphrey's "Justice of the Peace," 6th edition, gives the following quotation from the Petty Sessions (a Stamps Act, 21 and 22 Vic., c. 100, 32nd Aug., '53, sec. 14: "Every document enumerated in the Schedule (C) to this Act annexed shall, after the 1st day of January, 1859, be printed or written upon paper bearing a stamp denoting the amount or value set opposite to such document in that Schedule; and where any such document shall consist of more than one sheet, the first sheet only shall be impressed with the stamp; and no fees other than those contained in the Schedule (C), nor any stamp duties shall be payable in respect of any of the documents therein enumerated."

SCHEDULE C.

"On every solemn declaration (not being a declaration as to loss or pawnbroker's duplicates, or as to admission of paupers to work-houses)."

Nothing can be discovered in Humphrey's "Justice" or Levinge's "Justice" to authorise or warrant the receiving of fees by magistrates. A Justice will do wisely to be very cautious, and be sure that he is justified before accepting fees or donations. Heavy fines and removal from the Commission have followed indiscretion.—Ed.]

Vacancies.

Downpatrick Union, Portaferry Dispensary.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election August 8th.
Dudley Dispensary.—Resident Medical Officer. Salary commencing at £130. Applications before August 15th, to the Hon. Secretary.
Earlswood Asylum.—Medical Superintendent. Salary, £400, with extras. Applications, endorsed "Medical Superintendent," to be sent to the Secretary, 35 King William Street, London, E.C., before August 21st.

North Stafford Infirmary.—House Physician. Salary commencing at £100, with board. Applications to the Secretary, at Hartshill, Stoke-on-Trent, before August 23.

Royal Isle of Wight Infirmary, Ryde.—House Surgeon and Secretary. Salary, £50, with board, &c. Applications to be sent to the Secretary before August 8th.

Tunbridge Wells Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Secretary before August 9th.

Wrexham Infirmary.—House Surgeon. Salary, £100, without board. Applications to the Secretary before August 8th.

Appointments.

DYER, H. G., M.R.C.S., L.R.C.P., Medical Officer to the Ringwood Union and Workhouse.
EYANS, F. W., M.D., M.R.C.S., Certifying Factory Surgeon for the Cardiff District.

GOWAN, C., M.D., C.M., L.R.C.S. Ed., Medical Officer for the Newtown District of the Llanidloes Union.

MACKEW, S., M.B., Assistant Medical Officer to the Roxburgh, Berwick, and Selkirk District Asylum, Melrose.

THOMPSON, J. A. B., M.D., C.M. Glas., Medical Officer to the Middleton Cheney District of the Banbury Union.

VIVIAN, G. E., M.R.C.S., Medical Officer for the Alne District of the Easingwold Union.

WHITE, E. A., M.D., M.C. Aber., Medical Officer for the Third District of the Malmesbury Union.

WILLIAMS, C. L.S.A. Lond., Medical Officer for the First District of the Epsom Union.

WILSON, J. A., M.B., C.M., Assistant Medical Officer to the Govan Poorhouse and Asylum, Merryflatts, Govan.

Births.

LAST-SMITH.—July 27th, at Mayfield, Torquay, the wife of Edward Last-Smith, L.R.C.P., L.R.C.S. Ed., of a daughter.

REDMOND.—July 22nd, at 23 Victoria Street, Dublin, the wife of Dr. T. O'C. Redmond, of a son.

Marriages.

COLEMAN—MCKIE.—July 27th, at St. Augustine's, Highbury, N., Chas. A. Coleman, M.D., of Streatham, to Jessie, daughter of the late Thos. McKie, of Halifax.

Deaths.

BRIDGFORD.—At Bray, Charles Trussell Bridgford, M.D.

FITZPATRICK.—July 18th, at his residence, Maryborough, Archibald Fitzpatrick, M.D., aged 90.

ELKINS.—July 21st, suddenly, at Erdington, near Birmingham, Chas. Elkins, M.R.C.S., of Weston-super-Mare, aged 78.

POPPLTON.—July 25th, at The Grange, Horsforth, Leeds, Joe William Poppleton, F.R.C.S. Lond., aged 67.

WOODWARD.—July 25th, at King's Lynn, Edwin Woodward, [L.R.C.P.] in his 48th year.

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE V.

MR. PRESIDENT AND GENTLEMEN,—In reference to malignant new growths it is possible to use the word *diathesis* as applicable to two different things. We may mean a state of tissue-health giving proclivity to cancer, or the state which results from the existence of cancer. I will ask permission to employ the word cancer in its old and popular sense, as including malignant new growths of all kinds. This is the sense in which it has been used for centuries, and it is, I think, a pity that it should be changed, especially as we have in carcinoma, as opposed to sarcoma, a very convenient term by which to distinguish for scientific purposes certain forms of malignant new growths from others. In examining as to diathesis we must merge all the distinctions which have been established by the splendid labours of modern histologists, and speak of malignant new growths as one family. Indeed, it is by no means improbable that some forms of new growth not counted as malignant ought in this matter to be placed with those which are so, and that we should estimate the individual tendency to new growth in general without paying too much regard to differences in quality. We not infrequently observe that some persons display more than one form, and when hereditary transmission occurs it is very common to see it produce a growth of a different kind. On this doctrine of transmutation in transmission I had much to say in my last year's lectures.

The term diathesis is, I think, to be repudiated, as not suitable in reference to liability to the general diffusion, local recurrence, and failure of health which the existence of can-

cerous growth produces. These are all the direct and immediate effects of the disease, part of it, and are better named the cancerous dyscrasia. The real question before us is whether there exists any peculiar state of health wholly antecedent to the development of any local growth, and which gives proclivity to it. If such exists, and especially if it be in any way recognisable, the term diathesis may be conveniently applied to it. The first observation to be made in reply to this question is that cancer in the main is obviously dependent upon age, that it is in nine cases out of ten part of senility—a sort of second childhood of the tissues. Amongst the lower animals yet more than with ourselves cancers are, I believe, almost always the appanage of age. Old dogs and old cats get cancer of the lip or mamma, but these maladies are scarcely ever seen in young animals. When new growths which approach the malignant type are met with in the young there is probably almost always a history of inheritance. If we admit this statement we admit at the same time that there is a cancerous diathesis, since it is clear that a state of health may be transmitted which gives proclivity to the disease without actual conveyance of the cell germs of the new growth. The probability that such states of tissue-health exist is to be increased when we take cognisance of the numerous cases in which with hereditary history no manifestation occurs until adult or even senile periods of life are reached, though it must be admitted that these facts may be held to be evidence in both directions. We shall probably be not far from the truth if we admit senility of tissues, local or general, to be the one predisposing cause of cancer with which we are acquainted, and injuries and all forms of local irritation to be its exciting causes. A little step further may next be taken, in the belief that everything which tends to hasten senility, either local or general, will increase the predisposing influence, and in this category may be placed anxiety, distress, over-work, and excesses of all kinds. It is highly probable that under such conditions a state involving increased proneness to cancer may be induced, and further, that if offspring are produced after that state has been developed, they will inherit that tendency. This leads me to say a few words as to the last-suggested cause of diathesis which I have placed in my list. It may have seemed strange to some that it should have been suggested that senile changes can ever produce anything worthy of the name. It was by no means my intention to propose to rechristen old age by the name diathesis. What had occurred to me was rather this: Are there not conditions of tendency to premature old age which amount

almost to disease, and which are sometimes observed to run in families? The results are simply general tissue degeneration, atrophies, arcus senilis, white hair, pale blood, and general failure of nutrition, and yet the causes are to be sought among the ordinary causes of disease. Both arcus senilis and white hair, when met with, as they sometimes are, early in life in many members of the same family, and wholly without any accompanying signs of senility, may be held to rank as idiosyncrasies of tissue, simply little or nothing as regards the future. But there are many cases in which they are attended by other conditions, and in which they imply much. It is possible that arcus senilis may be in the course of hereditary transmission sometimes wholly detached from the state of health which produced it, and may become, as we have suggested, that hæmophilias and xanthelasma sometimes are heritable *per se*. More usually, however, it is probable that other conditions, such as tendency to arterial disease, accompany it, and that the total result is a state of premature senility. Certainly there are families in which a tendency runs to early senility rather than to any specific disease. I recently had occasion to amputate the lower extremity for senile gangrene of the foot of a gentleman who was barely fifty, but in whom general calcification of the arteries had proceeded to an extreme. I cannot but think that it would be convenient to recognise as a diathesis the state in which premature senility amounts to a disease.

I wish next to ask attention to certain laws as to persistence, self-aggravation, and recurrence, under which morbid processes due in the first instance to simple causes, or possibly quite accidental, may in the end breed diathesis. The best examples of this which I shall be able to find will perhaps be in such maladies as catarrh, erysipelas, and elephantiasis. Indeed, in what I said as to carbuncle, diphtheria, and erysipelas, I have already glanced at it. In our last lecture I contended that the specific fevers, in virtue of their own specificity, and that they are intrusions from without rather than modifications of existing elements and processes, possess no power of originating pathological habit, and thus do not become the parents of diatheses which are permanent. After a longer or shorter time their influence ends. In the instance of syphilis the length of reign is undoubtedly prolonged; still it does eventually terminate, and terminate completely. In my argument on this point I suggested that there was an essential difference in respect to this between inflammation which begins from particulate contagia and those set up by other influences, inasmuch as the latter do tend by the mere fact of existence to develop what we call pathological habit, and to increase in power by the mere fact of possession. It is, of course, not meant that they always do so, for fortunately there are other vital forces which are constantly working in other directions and tending to the restoration of health. What I wish to hint is that there is always a risk that an inflammation once experienced may become more or less habitual, and that its tendency is, if not counteracted, in that direction. In some of minor degree this is true probably of all inflammations, even of those which have been caused by injuries. There are several ways possible in which local inflammations or local injuries may become the causes of permanent change in the general health. They may in the first place, by the long-continued pain and irritation caused, reduce the nerve tone, and thus stamp a lasting impression on the cerebro-spinal part of the organisation; or secondly, by long persistence they may influence alike the blood and the nervous system. Sometimes it is not persistence so much as tendency to frequent recurrence which effects a similar mischief. Lastly, I shall have to maintain a theory that all inflammatory action is in itself infective, not to the same extent, but after the same pattern as malignant new growths. On this latter point permit me to go into a little detail before I proceed to the others. It is, I am sure, a fact familiar to all surgeons, that when acute periostitis attacks one bone, other bones are very prone to follow. Many years ago this curious fact attracted the attention of Mr. Simon, who wrote on it under the name of "necrosal fever." Distinctly the affection of the other bones is secondary to that of the one injured, and not simultaneous. There is usually a considerable interval, and further, those bones which suffer latest never suffer as severely as the first. It is exactly as if from the bone first inflamed some elements had been shed into the blood having the power to infect others. The bones affected secondarily may be in no structural connection with the first attacked—may, indeed, be a great distance from it. Thus, I have seen it begin in the tibia and occur secondarily in the humerus,

scapula, and ulna. The risk of implication of other bones exists only during the early stages of the disease, and is, I think, very seldom witnessed after the first fortnight. Mr. Simon's term, "necrosal fever," might perhaps suggest similarity with the form of multiple acute arthritis which we name *rheumatic fever*. In the latter, however, many joints are affected simultaneously and symmetrically, and all suffer in equal severity. In these features rheumatic fever differs much from what I have been just describing, and suggests that the different joints are affected independently of each other and from a cause common to them all. It is quite possible, however, that even in rheumatic fever the law to which I have adverted may be in force. We may remember that sometimes the arthritis does for a short time restrict itself to a few joints, or even to one, and that often some joints which escape at first suffer later on, whilst the implication of the heart never happens until a considerable time after the first outbreak in the joints. These facts would fit well with the theory that the parts first inflamed contaminate the blood and become the causes of inflammation of similar tissues elsewhere. It may be that it differs chiefly from necrosal fever in that the process is much more rapidly accomplished. At any rate as regards multiple periostitis we may be sure that in it the multiplicity is not to be explained by supposing that there is from the beginning some common cause, since in nine cases out of ten the inflammation of the bone first effected was caused by an injury. All who had paid attention to the development of eczema cases will, I am sure, bear out what I am now going to assert. It is very common for eczema to begin locally from a known local cause, such as the use of an irritating lotion or poultice, the employment of washing powders, or exposure to heat, and for the eruption subsequently to become general. It is possible that the restriction to the part first affected may be very short, or, on the other hand, it may be very long. I feel that I may almost venture to extend the scope of my first assertions and to say that I believe that it is rare for a local eczema, if allowed to persist, not to become sooner or later a general disease. It would be easy to collect instances innumerable in which eczema beginning around an ulcer on one leg has been followed by eczema on the other quite independently of any ulceration. It is not extension by continuity of tissue, or even by contiguity, but reproduction of the same type of inflammatory action in the same tissue at a distant part. In almost all cases of general eczema there is the history of an early period in which it was restricted to one part. I have several times seen disease of the finger-nails (chronic onychitis) appear on several fingers and on both hands, apparently in consequence of an injury to one. In these instances there is always I think a long interval between the injury and the affection of the other fingers, and during the interval the injured nail has always remained in a state of chronic inflammation. A gentleman who had consulted me a few weeks ago from thickened and opaque nails, and in whom several on both hands were in various degrees affected, told me respecting one which in no respect differed from the others: "Oh, that has been so for thirty years, it was from a crush." I found that the crushed finger nail had been diseased for twenty years before the others began to suffer. He had no skin disease, nor was there any history of such in his family, but I must add that he believed that his grandfather had had some affection of the finger nails. It will be thought by many that this latter fact deprives the case of its supposed significance and reduces it to simply an example of hereditary tendency. I have no doubt that in most cases in which local inflammation shows a power of contaminating the system we must acknowledge the existence of a predisposing cause as well as the exciting one, and it is to this rôle chiefly that I should like to assign inheritance in the first case narrated. No doubt the cases in which local eczema becomes general happen in persons who have a proclivity to eczema, but this fact only reduces and by no means takes away the importance of the exciting cause, since without it in all probability the morbid phenomena would never have come into existence. The occurrence of eczema in any part and in connection with any local cause, must rank as a revealing symptom to this extent that it makes known the fact that its subject is one liable to eczema but of itself next, if what I have suggested be correct must rank as a cause, and a very efficient cause, of aggravation of the previously existing proclivities. Under this suggested law of self-aggravation the permitted persistence of any local disease may become a source of danger just as

we well know the permitted persistence of a malignant growth constantly does. Nor surely is there any *a priori* reason why the life tendencies of inflammatory products and of those of new growths should be wholly dissimilar in this respect. Amongst other instances of maladies which often begin simply and locally and subsequently become multiple or general, we have boils, sycois, common lupus, various scrofulous affections, and certain forms of rheumatism. Respecting all these I believe that it is true that if they are cured after having persisted a long time the patient remains far more liable than others to a fresh development. In some sort a diathesis has been produced. In the case of periostitis I have seen some remarkable examples of this.

TWO CASES OF ATRESIA VAGINÆ.

By J. HALLIDAY CROOM, M.D., F.R.C.P., F.R.C.S.E.,
Physician to the Royal Maternity Hospital; Lecturer on Midwifery in
the School of Medicine; Vice-President Obstetrical Society, Edinburgh.

THE following two cases of atresia vaginæ, offering, as they do, several points of interest, appear to me worthy of record.

H. B., æt. 16, was seen by Dr. Alexander Moir in March last. She was suffering from acute pain all over the pelvic region, accompanied by vomiting and tenesmus. On examination, the abdomen was swollen, tense, and tender, and as she complained of bearing down pain on the inside of the thighs, Dr. Moir proceeded to make an examination in the region of the anus and perineum, and found projecting from the vulva a large, firm, tense tumour about the size of a large apple.

I saw the patient with him the same evening, and found the condition as described, and, in addition, made out distinct supra-pubic swelling, extending into the right ovarian region as far up as nearly to the brim of the false pelvis.

He got the following history from the patient's friends:—She had suffered as an infant from infantile paralysis of the left leg, which still remains comparatively useless and atrophic. She had never menstruated, but for the last thirteen months, at regular intervals, she has suffered from pain and discomfort, sometimes associated with tenesmus; otherwise she had been in good health. She had never suffered from any red discharge from any other part of the body.

The following day she was brought to St. Luke's Home, and an examination was made, when it was found that the vulvar tumour was slightly diminished in size and less tense, and that blood was escaping from the sides of the urethra.

The accompanying woodcut shows the appearances presented.

During the two following days blood escaped slowly from this aperture, and at the same time the supra-pubic swelling gradually diminished. *Per rectum* there could be felt but small space between the anterior rectal wall and anterior vaginal wall. The cervix could be felt continuous with the supra-pubic swelling.

The patient was allowed to pass over this period without any interference, and four days after the menstrual period a careful examination of her was made.

The supra-pubic tumour had disappeared, it had evidently been the enlarged uterus, and on recto-abdominal examination it could be found to be about the size of an orange. The most careful examination of the thick hymen failed to detect absolutely any opening, and *per rectum*, and with the finger in the bladder, scarcely any thickness of septum could be detected.

At next menstrual period careful observation was made of the part at which the blood escaped, and there could be no doubt that it was from the urethra. Various attempts were made with the finest probes to find an opening amongst the many lacunæ in the thickened hymen; but no such opening could be discovered. The urethra was dilated with Tait's dilators, and a careful vesico-rectal examination made out the uterine neck, and but a very limited area between the fingers.

The points of interest here therefore are two—

1. Escape of the menstrual fluid *per urethram*. This apparently came about in the following way:—The menses secreted in the uterine cavity, flowed no doubt into the small vagina, and met with obstruction from the thick tough hymen, and when the tension on the hymen was at its greatest, some part of the urethral septum, which in this case must have been weaker than the thickened hymen, gave way, and hence the patient menstruated through the urethra.

If the question be asked, "How was it that the opening in the urethra was not noticed?" the answer is simple: In such a case, not only is the opening through which the menses escape very small, but, what is of more importance, it is valvular. Hence its detection in the mucous membrane of the urethra will be difficult. This valvular nature of the opening is well illustrated in the case which follows.

2. The next point of interest is the apparently rapid involution of the uterus. This is a point which is well worthy of some study, because here we have the uterus getting only slowly distended, its distension to the size noted extending over a period of twelve months, and the uterus returning to little over its normal size within four days after being emptied, and that without any appreciable uterine contractions.

That the supra-pubic swelling was uterine, and not, as it often is in such cases, merely a stretching of the vagina, was proved by my first abdomino-rectal examination, when I could feel the cervix and tumour continuous, and further, as the tumour diminished I could make out the outline of the uterus.

It is further of note that although there had been accumulation of menstrual fluid for at least twelve months, and although it is well recognised that the puncture and withdrawal of the retained menses is often a dangerous, and sometimes a fatal, operation, yet, in the present case, the escape of the menses was unaccompanied by any disturbance. Probably this favourable issue was due to the remarkably small opening through which the menses passed, and that the opening was valvular, preventing the ingress of air and the consequent putrefaction of the fluid, as well as the fact that, even had the fluid been putrid, the raw surface for septic absorption was extremely small. Septicæmia and septic peritonitis are by no means infrequent causes of death after interference for this malformation.

Prof. A. R. Simpson, in his contributions to obstetrics and gynecology, records a case of imperforate hymen, with retained menses, where he endeavoured to meet the difficulty by penetrating the hymen with a fine incandescent

wire. The case he records, and which I saw, was most successful.

CASE II.—Some years ago I saw this girl, and found her suffering from a tumour in the left iliac fossa, and a bulging imperforate hymen. She had not menstruated, and was at that time aged 16. The hymen was punctured and the tarry menstrual fluid allowed to escape gradually. The girl made an excellent recovery. She went to her work ten days after the operation apparently in good health, and although she was urged to come and get the opening further enlarged, she did not return. The operation was done in dispensary practice with the poorest surroundings. The puncture was made to relieve the necessities of the moment, and a careful examination was not made, as I hoped to secure that more accurately at the dispensary afterwards. During last winter, after the lapse of five years, the girl consulted me as to the propriety of her getting married. She had menstruated regularly all that time without pain. On examination, I found the remains of the hymen, and an inch higher up the vagina was occluded by a well-marked septum, which was firm and unyielding. The septum was divided into two fornices: the left one shallow, and admitting the tip of the forefinger; the right one deep and narrow, into which the forefinger could not be introduced. On examination carefully with the small end of a duckbill speculum, the entire roof of the left fornix could be seen, and no aperture of any kind could be distinguished. It was impossible to inspect the right fornix by means of any form of speculum, nor was it possible to pass the sound. Even the finest probe would not pass up. Nor was I able, during the time of her residence in the Home, to get even a fine whalebone probe passed; and yet the menstrual fluid, during her next menstrual period, could be seen escaping slowly from the apex of the smaller fornix. The opening being small and apparently valvular. The uterus, by means of a recto-vesical examination, could be found retroverted, and the space between the cervix and the septum just described very small.

Such vaginal septa are common, and atresia vaginæ caused by septa some distance along the vagina is by no means rare, as is shown by Breisky in his work on the vagina. The peculiarity of the present case consists in the fact that the atresia consisted mainly and primarily in the condition of the hymen, the secondary atresia formed by the septum some distance along the vagina being only discovered some years after, and, as it were, by accident. As the record shows, it formed no obstacle to menstruation.

The formation of such a septum in the vagina is somewhat difficult of explanation. The first thing that occurs to one is, could the septum not be formed by the remains of the hymen becoming atrophied and shrivelled. This is not likely, as the remains of the hymen could be seen. Two suggestions occur:—

1. That it may have been the remains of some plastic inflammation arising after escape of the menstrual fluid five years ago; or else, which is possible, that
2. The condition may have been congenital, for I have no recollection of examining the uterus per vaginam at the time of puncturing the hymen. This would be brought about, if congenital, by an imperfect cleavage of the anterior perineal segment at the period of sexual differentiation in the uterus. In any case the condition did not appear to me to admit of any treatment, and was, in my opinion, a sufficient reason for celibacy.

WE are requested to announce that a meeting of Fellows of the Royal College of Surgeons of England will be held in the Assembly Room, Guildhall, Worcester, on Thursday, August 10th, to consider matters affecting the interests of the Fellows generally. The chair will be taken at 1 p.m. by Mr. C. G. Wheelhouse.

THE CHINESE MATERIA MEDIOA.

By FREDERICK NEWCOME, F.S.S.

(Continued from page 90.)

THE opium question is far too wide to enter upon except as a separate discussion, but two points wholly outside the bitter controversy are worth noting. A consensus of opinion is agreed that home grown opium (Szechwan opium chiefly) exercises on the natives very few of the debilitating and enervating effects attributed to the Indian article. Imperial restrictions upon its cultivation are rapidly being withdrawn, and although not so pleasant to the taste as Patna, or Benares, not to say anything of fine Malwa, its superior cheapness is securing it increasing support. Besides, the native cultivators are daily discovering improved methods of culture, imparting to it a superior flavour. When this difficulty is overcome and native opium can rival Benares in taste, the Indian opium question is very likely to solve itself by the almost total cessation of trade. Existing edicts, already ignored in parts, will soon be erased everywhere when hundreds of square miles will be given over at once to the poppy. Against the low prices then ruling Indian shippers will be incapable of contending, and this trade, like that of indigo, will gradually subside into absolute insignificance. Anti-opium pills and anti-opium powders form our second theme. These are presumably manufactured for the benefit of opium-smokers, in whom the pills are supposed to create a distaste for the seductive drug, but whether they act to his benefit or detriment is somewhat an open question. Mr. Lay remarks: "Confidence in the power of the pill to check the habit induces extra indulgence in the pipe, and the recreation is often divided between the pipe and the pill, to the manifest detriment of the system generally. A person may bear up against the effects of the pipe, but it must require a strong constitution to cope with the pipe and pill together, and it frequently happens that where the resolution is not strong enough at the outset to withstand the pipe, the victim succumbs to the treatment that he lays out for himself. If he has not a will enough to eschew the pipe, let him avoid the pills, as the two combined are not unlikely to bring on an attack of diarrhoea or dysentery, either of which to an opium-smoker indicates danger. An official who died in this region in the early part of 1878 is said to have succumbed to the use of anti-opium medicine. At times the pipe gave way to the medicine, then the medicine gained the upper hand, and this treatment was varied until Nature rebelled against it and the man was carried off by an internal disorder which set in." Unfortunately, we are not told the *recipe* of this interesting drug.

The value of castor oil is not unknown to the Chinese, but for some reason they seldom use it, exporting nearly all that is made. In the interior they find another use for the *ricinus communis*, converting it into a most palatable esculent. Latterly, however, the use of Palma Christi oil as a drastic has considerably extended. Turmeric is used by them both as a dye and medicine, and in the latter capacity we may assume for much the same purposes as it was once considered useful in this country. Among other productions of the Empire are aniseed; cassia; cardamoms; liquorice; juniper berries; cinnabar, used medicinally as well as for manufacturing vermilion; arsenic, traded in without any restrictions whatever, and utilised solely for dressing arable lands or destroying grubs and worms; china root; potash; chillies; green and white alum, the latter being largely converted into false pearls at Peking. With the therapeutic properties of all of these the natives are quite conversant; equally so with the various oils in which they trade, such as juniper, sweet Basil, cassia, cassia-leaf, and peppermint, all of which serve some medicinal purpose or other. On the other hand, they take from foreign countries gamboge, and several balsams; for example, dragons' blood and benzoin; also the resins

olibanum and myrrh. These serve an infinity of purposes, both medicinal and sacrificial. Sulphuric acid is occasionally used in preparations, but mostly for dividing gold from Sycee silver, while gypsum takes the place of violet powders in toning down the rouge with which the fair ones of the Flowery land so liberally besmear themselves. We had almost forgotten to mention mallows, which enter largely into the domestic economy.

The production of aniseed in China is simply prodigious. In one district alone the crop is estimated at 1,500,000 lbs., indeed, this must be an under-estimate, almost as much leaving Pakhoi for foreign countries. Star aniseed is found in two districts in Kwangsi—first, Lunchow, on the borders of Annam, from whence the larger supply comes; and, secondly, that around Posé, on the West River, close to Yunnan. Aniseed oil is another great production of this province, about 120,000 lbs. weight being exported yearly by sea. A considerable quantity of aniseed is also grown in Yunnan. This, however, finds its way *via* Yarkand into India, where it is known as *Bādiyāne Khatāi*, or Chinese aniseed. The properties of aniseed and its oil are well known to the natives, by whom large quantities are consumed.

About Cassia, or cassia oil, it is unnecessary to say anything, their properties being so well understood, but the subjoined notice of cassia leaf oil will doubtless be acceptable. Only quite recently has it become an article of commerce. Mr. Piry, of Pakhoi, writing in 1880, remarks: "It has not been known for more than a couple of years at Pakhoi, and passing to Mocao, it was probably never spoken of in Customs reports. A sample was sent to Canton; no trade was found to be done there in this oil, which, it was stated, offered but a poor percentage of proper cassia oil, or bark oil. It is extracted from the leaves of the *Cinnamomum Cassia*, and exclusively manufactured at Yulin. A similar essential oil, I may remark, has for years been extracted at Ceylon from the Cinnamon leaves, and called *Oleum Cinnamomi Foliorum*. The following data are given about this Ceylon essential oil:—'This is a brown, viscid, essential oil, of clove-like odour, which is sometimes exported from Ceylon. It has been examined by Stenhouse (1854), who found it to have a specific gravity of 1.053, and to consist of a mixture of eugenic acid, with a neutral hydro carbon, having the formulæ $C_{10}H_{16}$. It also contains a small quantity of benzoic acid.'—(*Pharmacographia* of F. A. Plückiger and Daniel Hanbury, F.R.S., Page 474)."

Cassia Leaf Oil is said to be much darker, thicker, and of less odour and transparence than Canton Cassia Bark oil, the specific gravity of which is 1.066. Generally speaking, it seems to be considered of very little value, except for sale to foreigners. The natives, perhaps wisely, do not use it, adhering to the bark oil, although so many times dearer.

(To be continued.)

Clinical Records.

ST. MARY'S HOSPITAL.

Stricture of Urethra—Perineal Fistula—Extensive Sinuses in Perineum and Scrotum—Extravasation of Urine—Erysipelas—Operation—Cure.

Under the care of A. T. NORTON, F.R.C.S.

History.—Patient was in the 9th Lancers for fourteen years, and was invalided from the army three years ago. He has had a stricture for eleven years, and on two different periods he had catheters passed regularly for some weeks, but the stricture was not cured. He said treatment had to be stopped at one time because he could not stand it; in another, because an abscess formed on the thigh, ceased, "as the doctor said," by the catheterisation.

Patient thinks the stricture was caused by riding a particular young, bony horse. For some time he had to ride bare-backed, and shortly after this a "lump" appeared in

the perineum. This was opened. Rather later he has had trouble in passing his water. At that time all the water passed by the urethra.

About five weeks ago, without any fresh injury, another abscess formed in the perineum. It was very painful and tender until it burst, a few days after its first appearance. Discharge then began to come from the urethra, and soon after the water passed through the external openings in the perineum, which were three in number.

Patient has had gonorrhoea once badly; it continued for six months. It was some years after this that the stricture first appeared. Has not had syphilis, nor any other serious illness. Has always had good general health. When invalided in hospital from stricture, he had an abscess form on his thigh, which was opened. He was under treatment for this for seventeen weeks.

Patient has never been in the habit of drinking much.

Present Condition.—Is a well-nourished, big, muscular man; complexion and general look healthy. He has a stricture a little in front of the bulb of urethra, which will admit, by continued pressure, a No. 7 catheter.

There is an opening in the right side of perineum about a quarter of an inch long, about one and a-half inch in front of the anus, through which, if it is not stopped, urine passes when micturating. The fistula passes forwards to open into the urethra about three-quarters of an inch in front of the external opening; on the left of the median line there are three cicatrices—two at the root of scrotum, the third an inch or two further back. In each there is a slight sinus, which will admit a probe for a quarter of an inch, but there is no urinary discharge from them. Beneath one of the sinuses can be felt a hard lump, slightly fluctuating in one place. There are two scars of small incisions on the front of the left thigh, slightly contracted and depressed.

Nov. 12th.—Patient had catheter passed to-day, and had a rigor afterwards. He was rather badly affected by it.

R. Tinct. opii, m. x.;
Quina sulph., gr. v.;
Aqua, ℥ss. statim, et bis die.

15th.—Scrotum red and inflamed slightly. Decided rigor after passing catheter this evening. Pulse quick. Great depression. Poultice scrotum. Temp., even., 102.6.

16th.—There is much inflammation and swelling of the scrotum and penis to-day. Redness extends on to the groins and thighs. Patient says he feels so ill; is very flushed and hot. Tongue coated, with red papillae showing at tip and sides. Pulse, quick, 100, weak. Takes only milk and beef-tea. Sleeps badly. Temp., morn., 102.8; even., 104.2.

17th.—Temp. just before operation, 101.6. Inflammation spreading. Patient was taken into the theatre in the evening, and Mr. Norton, when the patient was under ether, passed a curved staff. He then cut down upon the urethra in the median line, making an incision about an inch and a-half long. Tissues cut through were thickened and cedematous. The urethra was opened to the same extent as the external opening. The scrotum was then punctured at the back in several places; slight amount of inflammatory lymph exuded from the punctures. A director was then passed into the sinuses, and these laid open; from the most anterior of those on the left a small quantity of pus escaped. There was very little bleeding. The openings were plugged with cotton wool, and when bleeding had stopped, a poultice was applied. Patient recovered well from the anæsthetic.

18th.—Temp., morn., 101.4; even., 102.8. Diet, simple: Soda-water; eggs, ij.; beef jelly, ℥j. Bowels open very freely this morning. Erysipelatous inflammation spreading on thighs and abdomen. Removed to isolation ward to-day. Tongue coated with white fur. Pulse quiet, 90, and not easily compressible.

19th.—Temp., morn., 102.4; even., 102.8. Ordered to be put in a warm bath for two days by Mr. Norton, the inflammation of the scrotum and penis having increased.

20th.—Patient has been in the bath since the evening of the 18th. Inflammation is spreading on the thigh and over the buttock, but the scrotum is slightly less inflamed and swollen. Takes milk and beef-tea, and eggs beaten up in

milk or tea well, with brandy. Sleep; a little. Shivering and complaining of cold. Anxious and painful expression; rather flushed. Tongue coated. Pulse regular, 85; small, but not easily compressed. Temp., morn., 103°6; even., 103.

22nd.—Patient was taken out of the bath last evening. To-day feels rather better. Pulse is weak; about 100. Tongue dry; red at edges. Sleeps little now and then. Redness disappearing from scrotum, but extending down thighs without oedema. Parts are now poulticed. Has not much pain. Water passes freely through the wound in the perineum, which now is healthy; little through the external meatus. Temp., morn., 100°8; even., 101°8.

23rd.—Patient rather better to-day. Had two hours in bath this morning. Redness about parts rather less. Tongue dry and coated. Pulse 90, weak and soft. Bowels open to-day. Temp., morn., 101°8; even., 104°8; later, 103.

24th.—Temp., morn., 100°6; even., 102°6. Diet—Chicken, bottled beer.

25th.—Temp., morn., 97°8; even., 100. The scrotum and penis are less swollen, and redness is fading away. Bowels are open regularly. Tongue is cleaner. Patient takes his food well.

26th.—Temp., morn., 98°6; even., 100.

27th.—Temp., morn., 90; even., 100.

29th.—Patient visibly better now. The erysipelas is going off, and redness has very much faded. The whole of the thighs are not poulticed, only the knees being reddened now. The wound in perineum is looking well. Pulse is quiet, weak, and soft; 100. Temp., morn., 97°8. Tongue clean and moist, little coated, slightly reddened. Appetite is fairly good as a rule. Bowels opened. A little urine comes through the natural opening. Patient sleeps well as a rule. Sometimes sweats very much, which keeps him awake.

30th.—Poultices left off, except to wound.

December 2nd.—Patient is improving very much, and now there is not much discharge from the opening in the perineum. He does not complain of pain, and sleeps and eats well. Water passes freely through the meatus externus. Temperature varies about 1½° in the day, being subnormal in the morning.

6th.—Yesterday Mr. Norton passed a No. 8 silver catheter without much difficulty, and drew off a small quantity of water. It gave a great deal of pain. The erysipelas has entirely subsided, and the poultices have been left off the legs. There is still some oedema of the skin on the penis and prepuce.

12th.—Patient is doing well, but feels weak, and is not very cheerful. General health good. Little water passes now through the median opening, and it is granulating up rapidly. The other sinuses do not seem inclined to heal. Patient passes water very frequently in small quantities at a time. He complains of scalding. Sometimes a quantity of thick discharge is passed with the urine, and at this time he has more irritation. Discharge in the urine is thick and flaky; proves to be pus on examination. Iodine injections into sinuses are continued. The sinus on the right is now an inch deep. On the left there is a depression, the base of which is filled with granulations, and from it sinuses are found to extend upwards. Patient was taken into the theatre in the afternoon, and Mr. Norton—when ether had been administered—passed a sharply curved short staff, and then cut down upon it, in the old median incision, with a scalpel, opening the old incision in order to prevent the water from passing the urethral passage, and thus entering the numerous sinuses of the scrotum. The staff was then withdrawn, and a No. 10 silver catheter passed. No. 12 was then passed. A director was then inserted into the sinuses, and these were slit up with a scalpel to their extreme limit. The openings were plugged with oiled lint.

13th.—Wounds looking well. No rise of temperature. Dressed with oiled lint, and syringed with carbolic lotion. All urine comes through perineal wound. Pulse weak; 95.

16th.—R Pot. brom., gr. xx;
Chloral hydrat., gr. x;
Aqua, ad., 5j. omni nocte.

17th.—Pulse stronger. Patient doing well; more comfortable. Healthy granulations beginning to form at bottom and sides of three wounds. Patient micturates rather less frequently. Urine scalds. General health good. Getting stronger. Repeat haust chloral hydrat., gr. xx.

20th.—Patient going on very well. Wounds syringed

and dressed as before with oiled lint. Fast filling up by healthy granulations. Small quantity of urine comes by natural passage now.

23rd.—Doing very well. Wound on right has completely closed, and is beginning to skin over. The left wound has nearly filled up, and the central incision is also closing, very little urine coming through this now. Patient can stop this and make all the urine pass by the natural passage when he likes.

26th.—The central wound has now quite healed, and no urine passes this way now. Granulations filling it are soft and flabby. Right wound nearly skinned over. Left beginning to skin over. Mr. Norton passed No. 10 silver catheter to-day with ease, and without much pain to patient.

30th.—The opening into urethra from perineum has closed, and patient passes a large-sized stream in ordinary way. He passes water frequently, and in small quantity at a time. Slight deposit of mucus and pus in water. Left wound nearly skinned over. Oiled lint dressing, with syringing continued.

Discharged cured on the 18th January.

Germany.

THE IMPERIAL GERMAN CONGRESS OF SURGERY.

As already mentioned in these columns, the Eleventh Congress of the German Society for Surgery was recently held in Berlin, the session lasting four days. The gathering was a brilliant affair, not only from the great number of distinguished men present, "*Namen von gutem alten Klang in der Chirurgie*," but also from the excellent quality of the work done.

In addition to the residents of Berlin, who were naturally present, there were amongst others Billroth (Vienna), Volkmann (Halle), Esmarch (Kiel), Thiersch (Leipzig), v. Bergmann and Riedinger (Wurzburg), Rosenbach (Göttingen), Trendelenburg (Bonn), Schönborn (Königsberg), and many others of European reputation. There were also strangers from Russia, Poland, France, England, Denmark, and other countries still more remote. The first meeting was held in the hall of the University of Berlin, under the presidency of Herr v. Langenbeck. The President thought it better for the Society that he should resign his office, having held it since its foundation, as he intended leaving Berlin in the autumn, but finally consented to retain it for one year longer. A proposal which would have been brought forward in the event of the distinguished President persisting in his resignation, viz., to elect him President for life in recognition of his distinguished services, was likewise withdrawn for the year.

ON BLOOD CHANGE IN ACUTE INFECTIOUS DISEASES.—

The first address was by Herr v. Bergmann (Wurzburg), "*On a Blood Change in Acute Infectious Diseases.*" It related to those infectious diseases in which the morbid position is multiplied indefinitely, and in which the danger consists in an enormous diminution in the number of white blood corpuscles. The diminution in number, he alleged, was brought about by invasion into them on the part of the introduced bacilli, and their subsequent destruction. He mentioned other agents as capable of producing like effects, namely, unformed ferments, as the juice of the stomach and intestinal glands. This peculiar condition explained, as he contended, the train of symptoms common to diseases which have been proved to have a parasitic origin—anthrax, tuberculosis, and relapsing fever—diseases which are characterised by high temperature, swelling of lymphatic glands, icteric tint, and rapid weakening of the heart.

THE TREATMENT OF GENU VALGUM.—Herr Schede, of Hamburg, then followed with a paper on the treatment of genu

Valgum, after which a discussion took place, in which Mitsaliez, of Vienna (Billroth's assistant), Sonnenburg (Berlin), Winiwarter, Bidder (Mannheim), and Langenbeck took part.

BATHS IN THE TREATMENT OF SURGICAL DISEASES.—A paper by Sonnenburg succeeded, entitled, "The Importance and Use of Permanent Baths in the Treatment of Surgical Diseases." The advantages he claimed for them were complete absence of pain during the employment of the baths; diminution of fever; removal of discharges; greater rapidity of the healing process; and the absence of traumatic diseases, which have never been observed. He spoke of this method of treatment as of inestimable value in a whole series of cases, particularly when there are large cavities in the neighbourhood of the pelvis, of the rectum, uterus, bladder, and abdominal cavity, for all cases of chronic caries and suppuration. It had specially proved its value after lithotomies, particularly after the high operation, where drainage is often difficult. Dr. Hagedorn (Magdeburg) had employed permanent bathing for 20 years in an operation for stone; he used it also for extensive burns and scalds, in phlegmon and fecal fistula. Herr Schede (Berlin) also spoke favourably of the method. Herr Sonnenburg completed his communication by stating that the proper temperature of the water varied in different cases. Hebra had left his patient in the water for from 2 to 300 days. He himself used the bath night and day. Herr Bardeleben reminded them of the proposal of Weber, of Halle, to add salt to the water, and had himself employed an addition of thymol 1-1000, or acetate of alumina.

CORROSIVE SUBLIMATE AS A SURGICAL DRESSING.—Herr Kümmell, of Hamburg, read the next paper, in which corrosive sublimate as a surgical dressing was discussed. As it had been proved to be such a very powerful germicide, the author determined to make use of it, in place of ordinary disinfectants—carbolic acid and thymol, and had been completely satisfied with its action. The strength used for bandages, &c., was $\frac{1}{2}$ per cent., and for washing out wounds, 1 in 2000.

THE ANTISEPTIC PROPERTIES OF TURF-MOULD.—The next paper was by Herr Neuber (Kiel) "On the Antiseptic Properties of Turf-mould." Since Sept., 1881, in Prof. Esmarch's clinic, all operation wounds have been dressed with iodoform gauze over which has been laid a cushion stuffed with mould. This has been permitted to stay on for weeks, generally until complete healing of the wound had taken place. He spoke of it as an excellent absorbent application. The author mentioned many other substances with which the cushions might be stuffed, such as bran, sand, ashes, particularly beechwood shavings, saw-dust, &c.

THYMOL DRESSINGS.—Herr Rauke (Groningen), read a paper in which he expressed the opinion that thymol gauze dressings held their ground, and that if, in some instances, they had failed to produce good results, it was because the thymol was of inferior quality.

THE RESORPTION OF IODOFORM.—The next paper read was one by Herr Zeller, of Berlin, on "Experiments on the Resorption of Iodoform." The experiments were made in view of the numerous cases of poisoning by iodoform, from the report of which, however, data as to the quantity of the poison absorbed were absent. He arrived at the following conclusions:—1. That resorption from the bowel is slow and incomplete; 2. That iodoform absorbed from the bowel never produces toxic effects; 3. That absorption from a wound surface cannot be estimated. The quantity of iodine entering the urine is small, but on the other hand, the quantity present in the blood is always considerable, whence the teaching is drawn that iodoform should never

be introduced into any wound cavity from which it cannot be removed in the moment of danger.

NAPHTHALINE DRESSINGS.—Herr E. Fischer (Strassburg), followed with a paper on "Naphthaline Dressings." He described naphthaline as a white crystallised body nearly insoluble in water, but soluble in ether. The curing of smoked viands depended to some extent on naphthaline. It had the power of quickly destroying micro-organisms, did not produce a scab like iodoform, "but allowed all secretions to pass quickly through like sand." In Strassburg the results obtained had been *splendentes*. Hollow wounds could be stuffed with it without unpleasant accidents or symptoms of intoxication. It had the power of destroying insects living on plants.

ODOFORM IN THE TREATMENT OF WOUNDS.—Herr S. Langenbeck (Berlin) read the next paper, which was on "The Value of Iodoform in the Treatment of Wounds, and on Healing under the Iodoform Scab." In the course of the address he mentioned two deaths that had taken place from iodoform poisoning in Berlin (15 gramm. had been used) after amputation of the breast. These deaths had produced a change in the method of using iodoform, and for two months (since the beginning of April) iodoform had not been brought into actual contact with the wound. The following is the method now employed:—After bleeding has ceased the wounded surface is carefully washed in a 5 per cent. solution of acid carbol., and after the laying in of a wide drainage tube it is closed by sutures. Over the whole surface is then placed fine earth (mullstreifen) powdered with iodoform; over this again gutta-percha tissue, wadding, and a light compress. The drainage tube is removed on the third day, the suture on the sixth or seventh, and usually the wound is quite healed by the seventh. There is no suppuration, no redness and swelling of the edges of the wound, no pain; and even when the drainage tube is dispensed with, when blood collects in the cavity of the wound, there is no aseptic fever as when Listerian dressings are used. The author believed that by the use of the iodoform-scab dressing plastic operation would undergo a great change. In the discussion which followed, Herr Mikuliez weighed the advantages and disadvantages of iodoform, and concluded that in those cases in which iodoform had appeared to do harm, the manner of its employment had been at fault. In Vienna it had never been more than sprinkled over the wound, and then not over recent ones. This had been specially avoided in wounds of the mamma and amputation stumps. The discussion was then joined in by several, including the well-known names of Küster, Schede, of Hamburg, Bardeleben, &c.

From the above hurried glance at the work of the Congress it will be seen that the principal aim of the German surgeons of the present day has been to accomplish the aseptic healing of wounds, and to do this after the safest and most convenient method. Much remains to be done; no method is perfect, for simplicity is the essence of perfection; and all our present methods of dealing with wounds are too far removed from simplicity to be anywhere near perfection. Yet, when perfection has been reached, when the royal road to surgical healing has been discovered wherein the wayfaring man, though a fool, shall not err, it will still be Listerism.

SURGEON-MAJOR R. W. JACKSON, C.B., who has been residing in Dublin, has left for Egypt, his services having been specially requested by Sir Garnet Wolseley.

British Medical Association.

FIFTIETH ANNUAL MEETING.

ERE these lines are in the hands of our readers the British Medical Association will have inaugurated its jubilee in the ancient city of Worcester.

PRESIDENT—BENJAMIN BARROW, F.R.C.S., Consulting Surgeon to the Royal Isle of Wight Infirmary.

PRESIDENT-ELECT—WILLIAM STRANGE, M.D., Senior Physician to the General Infirmary, Worcester.

HONORARY LOCAL SECRETARIES—GEORGE W. CROWE, M.D., Shaw Street, Worcester; H. C. MOORE, M.R.C.S., 7 King Street, Hereford; THELWELL PIKE, M.D., 2 Montpelier, Great Malvern.

HONORARY TREASURER—G. A. SHEPPARD, M.R.C.S., Worcester.

The following is the Programme of the proceedings for August 8th, 9th, 10th, and 11th, 1882:—

TUESDAY, AUGUST 8th.

The Session will commence with a meeting of the Committee of Council in the Committee Room, at the Guildhall, at 2.15 p.m.

At 3 p.m., meeting of the Council of 1881-82. (Council Room, Guildhall.)

At 4.15 p.m. there will be a short service in the Cathedral, with sermon by the Dean of Worcester. After which, a collection will be made in aid of the British Medical Benevolent Fund.

At 8 p.m. the first general meeting will be held, when the President will deliver his address. The Annual Report of Council and other business will then be taken. Tea and coffee will be served after the meeting.

WEDNESDAY, AUGUST 9th (Jubilee Day).

At 9.30 a.m., meeting of Council of 1882-93. (Council Room, Guildhall.)

At 11 a.m., second general meeting, when an Address in Medicine will be delivered by Dr. W. F. Wade, of Birmingham.

IN THE SECTION OF MEDICINE

The following subjects have been selected for discussion:—1. Dr. W. S. Playfair will open a discussion on the Systematic Treatment of Aggravated Hysteria and allied forms of Neurasthenic Disease. 2. Dr. Balfour on Chlorotic Murmurs. 3. Dr. Leech on the Treatment of Cardiac, Hepatic, and Renal Dropsy.

The office-bearers in this Section are:—*President*—Thos. Clifford Allbutt, M.D., F.R.S. *Vice-Presidents*—George W. Balfour, M.D.; William Henry Broadbent, M.D.; G. H. Philipson, M.D. *Secretaries*—Edwin Rickards, M.B., 14 Newhall Street, Birmingham; H. Ashby, M.D., 13 St. John Street, Manchester.

After the address in this Section a luncheon will be given at 1.30 p.m. by the Worcester and Hereford Branch to members of the Association (limited to 500), and afterwards presentation of bust of Sir Charles Hastings to the Mayor and Corporation of Worcester. (Great Hall, Shire Hall.)

At 3 to 5.30 p.m. sectional meetings.

At 7.45 p.m. there will be a special service in the Cathedral, at which, by permission of the Dean, Haydn's sacred oratorio, "The Creation," will be performed by the Philharmonic Society, assisted by members of the Worcester, Gloucester, and Hereford Choirs, and conducted by Mr. W. Done, organist to the Cathedral. A collection will be made in aid of the British Medical Benevolent Fund.

THURSDAY, AUGUST 10th.

At 9 a.m., meeting of the Committee of Council. (Committee Room off Assembly Room, Guildhall.)

At 10 a.m., third general meeting. Reports of Committees will be read and considered. (Assembly Room, Guildhall.)

At 11 a.m. the Address in Surgery will be delivered by Dr. Stokes, of Dublin.

IN THE SECTION OF SURGERY

The following subjects have been selected for discussion:—1. Mr. J. Greig Smith will open a discussion on Early Operative Treatment of Joint-disease as a Preventive

of Excision, in which it is hoped the influence of Antiseptics in Excisional Surgery will be discussed. 2. Mr. Howard Marsh will open a discussion on Bone-setting.

The office-bearers in this Section are:—*President*—Augustin Prichard, F.R.C.S. *Vice-Presidents*—T. W. Walsh, F.R.C.S.; Reginald Harrison, F.R.C.S.; T. H. Bartleet, M.B., F.R.C.S. *Secretaries*—F. E. Manby, F.R.C.S., 10 King Street, Wolverhampton; Richard Clement Lucas, M.B., F.R.C.S., 18 Finsbury Square, E.C.

From 2 to 5.30 p.m., sectional meetings.

At 6.30 p.m. the annual public dinner will be given; tickets (price 2s. for wine-takers, 1s. for abstainers) will not be issued later than 12 o'clock on the day of the dinner.

FRIDAY, AUGUST 11th.

From 9.30 to 11.30 a.m., sectional meetings.

At 11.30 a.m., concluding general meeting; reports of Committees. (Assembly Room, Guildhall.)

At 3 p.m., garden party, at Madresfield Court, Great Malvern, given by the Lord-Lieutenant and the Countess Beauchamp.

At 9 p.m. a *soirée* will be given by the President and Mr. G. W. Hastings, M.P.

THE SECTIONS.

Beside the Sections mentioned in the foregoing Programme there will be six others, in which no opening addresses will be delivered, but in which various subjects will be brought forward for discussion:—

OBSTETRIC MEDICINE.—(Committee Room Assembly Room, Guildhall.)—A discussion on Subinvolution of the Uterus, its causes, its relation to uterine disease, and its preventive treatment, will be opened by Dr. John Williams (London).

The office-bearers in this Section are:—*President*—William Leishman, M.D. *Vice-Presidents*—Henry Ververs, M.R.C.S.; J. G. Sinclair Coghill, M.D.; Arthur W. Edis, M.D. *Secretaries*—C. J. Cullingworth, M.D., 25 St. John Street, Manchester; Tom Bates, L.R.C.P., Worcester.

PUBLIC MEDICINE.—(Civil Court, Shire Hall.)—A discussion on the Public Medicine Aspects of the Alcohol Question will be opened by Dr. Norman Kerr (London). A discussion on the Notification of Infectious Diseases will take place in this Section.

The office-bearers in this Section are:—*President*—Alfred Carpenter, M.D. *Vice-Presidents*—Alfred Hill, M.D.; Horace Swete, M.D.; E. T. Wilson, M.B. *Secretaries*—Geo. Haynes Fosbrooke, jun., M.R.C.S., Bidford, Redditch; Francis Edward Atkinson, L.R.C.P., Settle, Yorkshire.

ANATOMY AND PHYSIOLOGY.—(North Wing Committee Room, Guildhall.)—Several papers have been promised, and tables will be provided for the exhibition of microscopic objects.

The office-bearers in this Section are:—*President*—George M. Humphry, M.D., F.R.S. *Vice-Presidents*—S. S. Roden, M.D.; Frank Payne, M.D.; Gerald Yeo, M.D. *Secretaries*—J. B. Haycraft, M.D., Mason's College, Birmingham; James Shuter, M.B., F.R.C.S., 58 New Broad Street, London.

PATHOLOGY.—(South Wing Committee Room, Guildhall.)—In this Section there will be: 1. A debate on the Morbid Anatomy and Pathology of Diabetes will be introduced by Dr. D. J. Hamilton, of Aberdeen. 2. Mr. Jonathan Hutchinson will open a debate on the Origin of Tumours. There will be a table for the exhibition of wet specimens connected with this Section in the room provided for the meeting. There will also be an exhibition of microscopic objects connected with pathology in the same room.

The office-bearers in this Section are:—*President*—J. Hughlings Jackson, M.D., F.R.S. *Vice-Presidents*—W. R. Gowers, M.D.; H. T. Butlin, F.R.C.S.; Wm. Smith Greenfield, M.D. *Secretaries*—Sidney Coupland, M.D., 14 Weymouth Street, London; F. Treves, F.R.C.S., 18 Gordon Square, London.

OPHTHALMOLOGY.—(County Grand Jury Room, Shire Hall.)—The subjects in this Section are: 1. Dr. Edwyn Andrew will open a discussion on Extraction of Senile Cataract in its Capsule: modes of procedure. 2. A discussion on the following subject will be opened by Mr. E. Nettleship: To what extent do the signs derived from the examination of the Eye and its Appendages contribute to the localisation of Central Nervous Diseases?

Mr. Juler will exhibit Microscopic Sections of Diseases of the Eye. Mr. Juler and Mr. Anderson Critchett will exhibit the New Ophthalmometer of Javal and Schiotz for detecting Corneal Astigmatism, &c.

The office-bearers in this Section are:—*President*—James Voss Solomon, F.R.C.S. *Vice-Presidents*—David Everett, F.R.C.S.; Frederick Mason, F.R.C.S.; Edwyn Andrew, M.D. *Secretaries*—Geo. Edwin Hyde, L.R.C.P., Worcester; J. A. Nunneley, M.B., 22 Park Place, Leeds.

OTOLOGY.—(City Grand Jury Room, Shire Hall.)—In this Section a discussion on the connection between Diseases of the Ear and General Medicine will be opened by Mr. George P. Field; and a discussion on Auditory Vertigo, especially in regard to its Differential Diagnosis, will be opened by Dr. Woakes. Dr. Cresswell Baber will show an Aural Reflector and a set of Specula for the Waistcoat Pocket. Dr. Urban Pritchard will show a Convenient Form of Audiphone.

The office-bearers in this Section are:—*President*—W. Laidlaw Purves, M.D. *Vice-Presidents*—Geo. P. Field, M.R.C.S.; A. H. Jacob, M.D., Dublin; E. Cresswell Baber, M.B. *Secretaries*—J. J. Kirk Duncanson, M.D., 22 Drumahugh Gardens, Edinburgh; Peter McBride, M.D., 20 Alva Street, Edinburgh.

EXCURSIONS.

Worcester is proverbially famous for several manufactories of considerable artistic interest, all of which will be open to the inspection of members during the meeting. The following arrangements have been made for excursions at the conclusion of the meeting:—

SATURDAY, AUGUST 12th.

1. Excursion to Malvern Hills.—A train will leave Worcester, Foregate Street Station, at 9.39, arriving at Great Malvern at 10, where members lodging at Malvern can join the party. The geological structure of the hills and surrounding country will be explained by the Rev. W. S. Symonds, F.G.S., and G. H. Piper, Esq., on the spot. The return to Worcester can be made by any of the ordinary trains.

2. Excursion to the River Wye, Ross, Monmouth, Tintern Abbey, and Chepstow Castle.—A train will leave the Foregate Street Station about 9 a.m., calling at Malvern Link, Great Malvern, Hereford, and Ross Stations. At Ross boats can be hired for the River from Ross to Monmouth, passing through some of the most beautiful scenery of the Wye. The train will stop at Symonds Yat, Monmouth, Tintern, and Chepstow. Parties proceeding by boat from Ross to Monmouth can go on to Tintern and Chepstow by a later train to meet the party at Chepstow, when luncheon will be provided about 4 p.m.

3. Excursion to Stratford-on-Avon, Shakespeare's House, Museum, Church, &c.; Leamington, Kenilworth, and Warwick Castles.—A train will leave Worcester, Shrub Hill Station, at 9, arriving at Stratford at 10, where light refreshments will be provided by the medical men there. Thence, at about 12.30, to Leamington, where a luncheon, limited to 100 members, will be given by the members of the Association residing in Warwick, Leamington, and Kenilworth. From Leamington by carriages to Kenilworth Castle, thence to Warwick, leaving the latter place at 7 o'clock.

4. Excursion on the River Severn.—The steamer, *Lady Alynne*, will leave Worcester Bridge, at 10 o'clock, for a trip of about two hours to Tewkesbury. After allowing time for viewing the ancient Abbey, it will return to the "Shrubbery" in the grounds of W. Dowdeswell, Esq., where, by permission, luncheon will be provided. This excursion will not take place unless there be twenty-five members going.

Further particulars may be obtained of Dr. PIKE, Great Malvern, for the Malvern excursion; of Mr. H. MOORE, King Street, Hereford, for the Wye; and Dr. CROWE, Worcester, for the Stratford and Tewkesbury excursions.

We rejoice to learn that last week the Committee on the Contagious Diseases Acts finally decided by nine votes to six, to adopt Mr. O'Shaughnessy's report recommending the renewal of the Acts.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

SEGREGATION IN CONTAGIOUS DISEASES.—The Académie de Médecine having been requested by the Minister of Public Instruction to give its opinion "on the time that a pupil affected with contagious disease should be separated from his comrades," formed a committee to study the question. Last week the report of the committee was read before the Academy by M. Hillairet. The reporter enumerates the contagious diseases most commonly observed in schools, such as cow-pox, small-pox, scarlatina, measles, mumps, and diphtheria. Cow-pox being sometimes very irregular in its mode of progress, would in certain cases last ten or twelve days. It takes eight to ten days for the crusts to fall off. The isolation should last twenty-five days. Small-pox has a prodromic period of three or four days, that of the eruption lasts from four to five; that of the suppuration of the pustules from three to four; desiccation requires three days; the fall of the crusts six days, which is followed by a period of furfuraceous desquamation, of which the duration is not well defined. Forty days should be fixed as an average for the isolation. In scarlatina the period of invasion is from six to forty-eight hours, sometimes, but very rarely, three days. The eruption takes five or six days, and the desquamation commences the fourteenth or fifteenth day. Here also forty days should be allowed for isolation, and the same period will be necessary for measles. Twenty-five days will be sufficient for mumps, while diphtheria will require forty days. M. Hillairet insisted that the isolation should be absolute, and before the patient should be allowed to join the class he should take a couple of warm baths. His clothes should be placed in a properly heated oven 90 degs. C., and submitted to sulphur fumigations. The bed and bedding should be entirely disinfected, washed, and aired. These conclusions were adopted by the Académie.

TREATMENT OF DISEASES OF THE RESPIRATORY ORGANS WITH THE CAUTERY.—M. Emile Vidal made a communication to the meeting on the treatment of diseases of the respiratory organs by the cauterization applied on multiplied points on the skin corresponding to the portion of the organ affected. These *points de feu* should be as numerous and superficial as possible, and might be renewed every two or three days. As effect of this treatment on the skin is observed redness, heat, and horripilation. These phenomena are not always limited to the part touched by the cauterization. Its effect on the respiratory organs was observed to consist in a positive diminution of the congestion, and, above all, an almost instantaneous arrest of hæmoptysis. Upon 44 patients treated by this method there were three deaths, two refused to continue the treatment, 36 were sensibly ameliorated, of which 23 were observed to have vomited. In eight cases the hæmorrhage was immediately arrested by cauterization.

USE OF PILOCARPINE.—In spite of the sweeping declaration of M. Germain Sée against the substance known as pilocarpine, cases have occurred in which the cure has been attributed, rightly or wrongly, to this remedy. The case is the following:—A man, aged 30, of vigorous constitution, entered La Charité, under the care of M. Peter, with a pleurisy of a fortnight's duration, and on examination it was found the right pleura was full. The following day thoracentesis was practised, giving issue to over a quart of non-purulent liquid. About the same quantity was left in, which three successive blisters failed to remove. Recourse to pilocarpine was decided upon, and two centigrammes, or two-fifths of a grain, was given in hypodermic injection, which gave origin to almost

immediately profuse perspiration, which lasted an hour and a quarter, and a salivation so abundant, that two spittoons were completely filled. All this time the patient was deprived of drink. A few hours afterwards examination showed that all the liquid had disappeared. There was no more dulness, and the respiration was normal the whole way down.

IODOFORM has been frequently employed in tuberculous disease, and not without effect. Several medical men have from time to time given publicity to their observations on the action of this agent, and have expressed themselves well satisfied with the result. Dr. Moor, of Paris, is a partisan of this medicine, and justly so if we may judge by the following case treated by him:—A woman who declared herself to have been 18 months ill, came to consult him. She was very weak, and auscultation and percussion left no doubt on the nature of the disease, which was well advanced. He ordered her tonics, and three of the following pills daily:—Dover's powder, 2 grs.; iodoform, 1 gr.; ext. gentian, 2 grs., for one pill. This treatment was continued eight months, at the end of which period the patient's health was fully established, and the vomica had totally disappeared. In a disease against which we have so few resources at our disposition, the administration of iodoform is worth a trial; in any case the idea of it cannot but be rational.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 9, 1882.

THE BRITISH MEDICAL ASSOCIATION AND ITS AIMS.

HOWEVER much the profession of medicine has happily advanced within the recollection of the present and the last preceding generations, it must without question be allowed that the influence exerted over it by voluntary

association of its members together has been mainly instrumental in effecting such progress. It may be truthfully avowed that without such influence we should still be holding a place in the world which but ill comports with the importance and the dignity of medicine; while, moreover, very much of the good work traceable to other than individual efforts would have remained unaccomplished. In this way, the meeting of which the town of Worcester is this week the scene deserves a more than usual recognition, as being the jubilee of what is the greatest and most protective of all British unions of physicians and surgeons. The work of the British Medical Association, nevertheless, cannot, we take it, be regarded as in any view complete or sufficient, for it hardly yet succeeds in that which it ought to be prominent in securing, viz., the cohesion of the medical profession. Spite of the bonds which unite its members in a common fellowship, it is too true that fellowship with them is but an empty name, and that in all that chiefly relates to preservation and augmentation of universal advantages, there is a painful and too evident lack. It is an ungenerous task to urge this at a moment when general jubilation marks the fiftieth birthday of a great society, and when it might be said that nothing less than joy and gratulation should mark our proceedings. But for the very reason that half a century of work appeals before us in behalf of claims the Association advances, it is fitting that omissions should be compared side by side with possibilities, and that in the moment of greatest satisfaction, hope of future achievements should be instilled by recognition of what achievements in the past have not been made.

And foremost among these is the fact of common experience and common regret, that the body of the profession is even yet, for all practical purposes, an ununited mass, an unreliable and incohesive assembly, and useless for such purposes as are served by the agreement of unanimity. Except it may be under circumstances of the kind that surrounded the recent prosecution of Dr. Ferrier, and when it was rather the pecuniary resources of the Association than its own inherent strength that stood him in good stead, we cannot say that the medical men of this country can make themselves heard as a great and a single voice. In a hundred ways just now the wayward utterances of public opinion might be inclined to directions which it is of the utmost moment they should be directed in, could it but be influenced thereto by the profession as a whole. In respect to vivisection, vaccination, extinction of contagious diseases, sanitary improvements, &c., &c., is this especially true; and it cannot be but that the British Medical Association is the source whence action having this tendency should emanate. But it is not so, in spite of all that seems the contrary, for its conclusions do not bear the stamp of being more than representative; they are never endowed with the force of edicts, because they are not edicts.

To the world the Association is, after all, only a large debating society, meeting once a year, and discussing within itself such details as are properly included in a programme of technical debates. Again and again has it been shown by the acts of a few of its members, however, and especially by the appointment of committees, that its

role is a wider and a greater one than this ; and they take the narrowest view of its functions who would contend that it has no duties in relation to the non-professional population. In only a little can it be said to have changed from what it was in its earliest days ; it has vastly extended the limits within which its work is accomplished, and, so far as excellence is concerned, the value of each year's contributions in the shape of papers is ample proof of continued progress. But the changing times have introduced changes without and beyond those merely of degree ; and to be in keeping with the changing necessities of to-day the Association ought to be adapted to meet requirements which, while existing now, were undreamt of at the period of its creation. These changes deal eminently with the world's advance, and are of a kind which should bring the medical profession as a body into closer relation as advisers and counsellors and directors with all mankind.

Conservatism may insist on the needlessness of such cautions, and that the proof of an admirable arrangement is to be found in what has already been accomplished. But surely such argument is fallacious in the extreme. Because we have succeeded in the past is it a reason why we should not yet further achieve in the future ? And that the British Medical Association may become the engine to achieve such progress there can be no doubt. It has been charged against it that its annual meetings have rather the character of a pleasant holiday outing than of a grave and serious gathering ; and the theory finds best countenance in the nature of its business transactions, which are without interest or bearing for the public mind. It is not sufficient that those who attend and take part in the work done at those meetings should be convinced of the value it possesses ; they only, then, and those who can follow with due intelligence reports of what takes place, can appreciate what is done ; there should be that about the transactions of the Association which should tie the sympathies of the people to its success, and prove to them the vital interest they possess in the proceedings of the brotherhood of medicine. As it stands now, other and, so to speak, illegitimate societies, absorb the attention and consideration which ought never to have been alienated from the most natural object on which they could have been bestowed, the medical profession as a whole. It is at least inappropriate that sanitarians should assume for their special care the health of the nation, which is first, and before all, the charge transferred to medical men. Even the Social Science Congress, when rightly considered, can hardly be regarded as beyond the limits of the field within which British medicine exercises protection ; and name it how we will, the profession is, collectively, the guardian of all that pertains to the physical welfare of the nation.

Too narrow limits have been, without consent, set to the aims and objects of the Association ; and it is time that emphasis were given to the view which would regard it as having a right to extend its action, for only so can we look for restitution to the profession of many of the functions now taken from it by usurping foreign authority. As concerns its obligations towards medicine pure and simple, the Association has abundantly fulfilled them ; and perhaps no branch of its work has been more prolific of good result than that presided over by the Scientific

Grants Committee. Indeed, it might very well be considered whether the amount expended in encouraging research by assisting investigators to meet the expenses incurred by their observations, should not be considerably augmented. Since the last meeting of the Association £325 have been voted by the Scientific Grants Committee, the largest sum going to Dr. C. S. Roy in furtherance of his studies in cardiac pathology. Another important research, one as to the elimination of nitrogen during labour, by Dr. Burdon Sanderson, has absorbed £25 ; and Dr. Thin receives a like sum in connection with his investigations on the presence of bacteria in the skin. Several of the researches remain incomplete, and will presumably receive additional aid ; it is certain that no more productive method of spending funds could be devised.

All will unite in wishing all hail ! to the Association, and in heartily congratulating it on the attainment of its fiftieth year ; all must wish also that henceforth may date an era not alone of greater usefulness within, but also of wider influence without.

THE ENGLISH MIDWIVES REGISTRATION BILL.

WE have received a copy of the "Registration of Midwives in England and Wales Draft Bill." In the first instance, the Bill proposes that a "Midwifery Board" shall be appointed by the General Medical Council, and that the vacancies occurring in the board shall be filled up by the Council. We have grave doubts as to the wisdom of placing this power in the hands of the Council exclusively, and certainly if it be finally decided to do so, members of the Council should, we think, be disqualified for seats on the Board.

The Board is to appoint a "general registrar," and also local registrars for each of the examination districts into which the country is to be divided, and a register is to be kept by the general registrar, which is to contain two lists of persons registered under the Act as midwives. The first, of persons who have passed the examination which is proposed to be held, and obtained a certificate from the Board ; the second, of all such persons as, for not less than twelve months prior to the passing of the Act, may have practised as a midwife, the only requisite in their case being that they obtain from "a qualified medical practitioner a certificate to the effect that he knows the applicant personally, and that she is competent to attend and take the care and charge of women in ordinary cases of labour."

The rest of the Bill is made up of details which it is unnecessary at the present time to enter on. It is quite impossible that this Bill, in its present shape, could pass into law. The chief objection to it is the clause enabling women already practising to be registered. The mass of these women are ignorant—many of them absolutely illiterate—and such should not, under any possible circumstances, be registered. Some, doubtless, should be ; but certainly none on such terms as this Bill indicates. By it any woman who has been about—it may be but one or two—lying-in women in their lives

could be put on the Register. Not only could be, but would be, for there would be no difficulty in obtaining from some practitioner so very vague a certificate as required by the Bill. The farthest we would go would be to exempt from any penalty women who could prove that they had been practising as midwives for five years prior to the passing of any Registration Act.

We are also disposed to fear that the powers of creating examining boards are too extensive. If they become numerous they will, in all probability, become worthless, for the downward competition to attract candidates would be very great in these days of cheap railway travelling. Six or eight examining boards for all England would be ample, and these only in towns where there would be an opportunity of selecting men properly qualified to be examiners.

But the whole scheme which aims at "registering midwives" will fail unless means be adopted, in the first instance, for insuring that these women be educated. If no proper education be given, the registration will be of little value. Men will soon be forthcoming who will be ready to pass any woman of moderate education in a few days; but though the candidates may thus be enabled to answer some questions, she will not be fitted to act as a midwife with safety to her patient. In Ireland matters are on a much better footing. In Dublin the Rotunda Hospital has, for a number of years, and the Coombe Hospital recently, been empowered to grant certificates to midwives educated within their walls, and hundreds of well-trained women are at present scattered over the country; and it is a disgrace to England that no really efficient training can be anywhere obtained by women who desire to act as midwives. This cannot be done by Act of Parliament; but till some effort be made in this direction in the great English towns, the mere registration of midwives will avail but little.

PRACTICALITY IN EXAMINATIONS.

DISSECTION.

THE propriety and possibility of substituting, in the examinations for licenses to practice, the actual work of the candidate's hand and finger for the *viva voce* explanations by him which are now the rule in some of the most important of the qualifying bodies, was raised as prominent subject for debate at the recent meeting of the General Medical Council, by the reports of the Visitors of Examinations, which were laid before that meeting. The Visitors had made it their first recommendation, "that every primary examination should include dissections by every candidate," and they added subsequently, "that in every final examination for a surgical diploma, candidates should be required to perform operations on the dead subject."

As to the propriety of requiring the candidate to answer upon a dissection executed by himself, the Visitors—in their report upon the examination of the London College of Surgeons, say: "Admirable for exactness and precision as is the mode of testing by question and answer on the carefully prepared dissections at this College, the Visitors feel that the knowledge thus tested and prepared for ex-

amination is but one step removed from knowledge obtained through the medium of books and plates. Besides, no candidate can dissect fairly at an examination without having dissected abundantly during his studentship, and there can be no doubt as to the relative value of anatomy remembered from personal dissection, as compared with anatomy remembered from plates or from dissections done by other persons. Again, the collateral advantages involved in becoming a practised dissector are so obvious that it is unnecessary to emphasise them. The difficulties have not proved insuperable in the case of the Irish College of Surgeons or the Glasgow Faculty."

Again, when criticising the examination for the L.R.C.S.I., the Visitors say:—"The Irish College of Surgeons was the first of the corporations to adopt this practical method of examination, and the Visitors think it would be well if the example were followed by other corporations, even though, in order to do so, they are obliged to augment their staff of examiners, or curtail some other portion of their examination. The mode of actual dissection gives the examiner facilities for determining the candidate's anatomical knowledge far greater than can be obtained from any amount of *viva voce* or answers to written questions. It should be remembered that the kind of information elicited by so practical a mode of examination is such as can hardly be obtained by any amount of mere reading or grinding, but must be derived solely from the industry and manipulative dexterity acquired by the candidate himself in the dissecting room. The impulse which this method gives to practical work in the dissecting-room is evident, as it must soon become known to all preparing for examination that only in the practical work of the dissecting-room can the information and personal skill in manipulation be obtained that it is the object of this examination to elicit. Seeing that one great object of an examination—may, even the greatest—is to direct study, the Visitors cannot but feel that the method which enforces the most valuable kind of study ought to be an essential factor in the testing of every candidate."

These remarks are so much to the point, and so well put, that it would not add to their force if we were to paraphrase them. The fairness of the arguments adduced, and the logical completeness of the entire criticism, leaves nothing to be desired, and we very heartily endorse the opinion as to the advantages of a practical dissection examination so well expressed.

It is, indeed, not easy to understand how anyone could dispute the propositions that the making of a good dissection is a better proof of knowledge than the explanation of a dissection made by others; nor does it seem possible to doubt that the student will be certain to learn to dissect if he knows that he will be required to do so when he comes to the examination table. And yet the Medical Council actually rejected a motion by Mr. Macnamara to declare that "every primary examination should include dissection by the candidate," and adopted the simple "recommendation" that such a method of examination is "desirable."

The opposition to practicalising the anatomical examination came from the Scotch Colleges, which, excepting the Glasgow Faculty, have no dissection test, and from the London College of Surgeons, whose examination is carried on by means of bottled preparations. Mr. Marshall (London College) observed that the majority of his Council approved the principle of the resolution, but the practicability of such a proceeding as that involved in the amendment was a question for serious consideration. Only mischief could result from carrying out the more drastic measure at the present time. If really carried out, the

plan would starve in the dissecting-room, and thus education would suffer. Prof. Turner opposed the proposal of Mr. Macnamara as being thoroughly impracticable. On the questioning of severity, also, he urged that sound examination could be conducted without practical tests. From personal experience, he felt assured that an examiner could form accurate ideas of the extent of candidates' practical knowledge of anatomy by examining them on the dissected parts. In Scotland the examiner's own personal knowledge of candidates formed an important means of assisting the estimate of each candidate's performance.

Prof. Humphry trusted the Council would not pass the impracticable resolution proposed by Mr. Macnamara. He cordially approved the plan of examining candidates in dissection wherever it could be followed; it helped the weaker candidates. It was not, however, he thought, an essential feature of a good anatomical test.

Dr. Watson (Edinburgh College of Surgeons) agreed with Mr. Turner that a practical examination in anatomy was not essential, and supported the resolution of Mr. Teale, but would modify it by adding that "where circumstances permit" the examination should be carried out.

It will be observed that the Scotch representatives simply contested the propriety of inquiring as to whether the candidate could or could not dissect, and they were apparently of opinion that a fair commercial article in the way of a medical practitioner, quite good enough for average purposes, could be turned out and put upon the market without any practical knowledge of anatomy. This proposition has the merit of simplicity, and also the advantage of satisfying the views of students who emigrate from England and Ireland to Scotland for licenses, and is, moreover, nicely compatible with the money interests of the Scotch College, but we do not expect that any of these reasons for approving such a proposition will convince those who wish to see no one licensed to practise save a competent, well instructed surgeon, who knows not only when and how to cut, but where his knife is going when he does so.

On the other hand, Mr. Marshall, on behalf of the London College of Surgeons, is content to take lower grounds, to admit that an examination without dissection by the candidate is defective and insufficient, and to plead that bad as the London examination is in this respect, it must continue to be bad, inasmuch as sufficient material for practical examination cannot possibly be obtained. We entirely dissent from the contention of the Scotch representatives, and from the calculations of the members for the London College of Surgeons. We fully believe that in this matter as in others "where there's a will there's a way," and that the licensing bodies could readily adopt Mr. Macnamara's proposition were it not that they do not desire to disturb comfortable arrangements, or to alienate claimants for their diplomas by undue severity of test.

The Special Committee which was appointed by the Council, on the motion of Dr. Lyons, M.P., to inquire into this alleged scarcity of subjects will, no doubt, set this latter question at rest; but even if it should appear that practical dissection is an impossibility in London, the fact will still remain that it is expedient, and that

any examination which omits it must be placed in a lower grade by reason of such omission.

Notes on Current Topics.

Darwin.

In the current number of the *Westminster Review* there is contained a careful and critical essay on the late Charles Darwin and his works. It will be read with much interest even by those who have perused the mass of obituary literature devoted to the immortal naturalist. It is marked by a style at once appreciative and impartial, and opens with an interesting sketch of the personal history of the illustrious author of the "Origin of Species." We may be forgiven for reproducing the following admirable judgment on Darwin:—"The life of Darwin is an epic. The object of his highest aspirations—of his earnest and diligent pursuit—was Truth. He followed ever where she led, or seemed to lead, and even when the path diverged from the beaten track and became entangled with briars and thorns, he still pushed on, undeterred by perils, seeing the beacon light afar. Luxury and ease invited him, but he rejected their allurements, and still pressed on. Enemies opposed his progress, and assailed him with every weapon in their power; but, like a skilful general, he allowed them to spend their strength in vain upon a fortress which he knew to be impregnable, and he triumphed. Yet, even in the hour of triumph he never lost that modesty which is the finest attribute of a seeker after truth, and even his bitterest enemy could never accuse him of arrogance or discourtesy."

Fulham Small-pox Hospital Report for 1881.

THE "Report of the Medical Superintendent of the Fulham Hospital for the year 1881" is a document of unusual interest, both on account of the excessive strain put upon the resources of the institution by reason of the late epidemic of small-pox, and because it contains an outline of the experience which have mainly induced Mr. Sweeting, the medical officer of the hospital, to formulate the conclusions adopted in his well-known memorandum. During the year there were 1,952 admissions, of whom 255 died, and 1,745 were discharged, leaving four cases under treatment at the end of last December. Of the admissions 1,790 were acute cases, 162 being convalescent from other hospitals, but 38 were not small-pox. It is reported that three cases came in public hackney cabs, and that during April 355 cases applied for by telegram could not be received, on account of no beds being available. It is highly satisfactory to read that the total percentage mortality in this large number of cases was no higher than 14.18, or calculated according to the Registrar-General's formula, 14.09, a figure which speaks convincingly for the excellence of the treatment and hygienic surroundings. Of the 1,752 "acute" cases, 1,355 were vaccinated, 187 "doubtful," and 210 unvaccinated. The mortality per cent. in the three classes thus distinguished was 7.30, 31.01, and 42.38 respectively. Respecting the immunity enjoyed by re-vaccinated persons, the statistics given with reference to the staff of the

hospital are remarkable. The total number of persons so employed since the hospital was opened is 295, of whom 42 had previously had small-pox, and only 5 out of the whole number took the disease; 69 fresh members of the staff were engaged during the year, the total number at one time being 80. *Not a single case of the disease occurred among them*; and that this striking exemption was not due to any want of susceptibility to fever was proved by the fact that ten of them took scarlet fever, which was accidentally introduced into the hospital. All these cases recovered after removal to Stockwell Fever Hospital. An undoubted case of small-pox incubated *in utero* is narrated; and in a table in the appendix is given a careful analysis of the complications and sequelæ observed in the patients. Mr. Sweeting makes reference to the vexatious hampering of the work of the hospital, owing to the attempts made to close it on the part of residents in the neighbourhood. The report is a valuable contribution to the literature of small-pox, and gives every indication of anxious and skilful management, which is especially testified to by the strikingly low death-rate for the year.

Nurses for Egypt.

IN view of the necessities that have arisen in consequence of the breaking out of hostilities in Egypt, a contingent of nurses, numbering 24, is to be sent out in the *Carthage*; they will be distributed among the stations at Gaza, Cyprus, and Ismailia, and a few will serve in the hospital ship. These nurses have been selected with the utmost care, and have given proof to the satisfaction of the Army Medical Department of their skill and experience in the treatment of the sick. Each one has been carefully trained, either at Netley or at Miss Nightingale's school, and during their period of foreign service they will all be subject to regular discipline as army nurses. It would be impossible to over-estimate the value of their presence, and it is a wise decision to which their appointment is due.

Infantile Earache.

IN the American Medical Association, Dr. Jacobi has recently remarked that closing the mouths of infants and children, and simply blowing into the nose, is often a very valuable method of relieving severe earache, and that in a number of cases he had obtained most excellent results from this procedure, the cause of the trouble probably being a catarrhal affection of the Eustachian tube.

The Social Science Congress.

AT the congress of this Association, to be held in Nottingham during the week from September 20th to 27th, the following questions will be discussed in the Health Department:—1. How does the employment of mothers in mills and manufactures influence infant mortality; and ought any, and if so what, restrictions to be placed on such employment? 2. What reforms are desirable in the administration of hospitals? 3. What are the advantages of a system of notification of infectious diseases, and what are the best means of carrying the same into execution?

The Hospital Sunday Fund.

THE Lord Mayor presided on Wednesday last over a meeting of the Council of the Hospital Sunday Fund, at the Mansion House, where the Distribution Committee presented their list of suggested awards, this including five institutions more than were scheduled last year, or 145 in all. The amount received up to July 18th was £32,424 12s. 2d. Four per cent. of this sum was apportioned to the purchase of surgical instruments, and when to this was added the amount due for expenses, a sum of £32,415 13s. 9d. remained for distribution. To 93 hospitals an aggregate of £28,446 15s. was allotted, and to 52 dispensaries £2,588 18s. 9d. Subscriptions received subsequently to the date of the report will be carried to the credit of next year's collection.

Redundant Titles.

UNDER this heading we recently found it necessary, our attention having been called to the practice by hospital surgeons who felt aggrieved thereby, to deprecate the use by an author of various titles which, though simply synonyms for the one appointment of hospital surgeon, were so used as to do duty for several separate offices. Thus, an author would sign himself "Surgeon to ——— Hospital;" "Teacher of Operative Surgery;" "Lecturer on Clinical Surgery;" when, in fact, he held but one appointment of which the functions of "Teacher" and "Lecturer" were a part.

We have been reminded in response to our observations that an hospital surgeon using these terms is, in fact, all that he represents himself to be, and that the practice we complain of is usual amongst authors, and we wish, therefore, to explain that what seems to us objectionable in the matter is the use of any words which imply a plurality of appointments. If an author designates himself "Surgeon and Lecturer on Operative and Clinical Surgery in the ——— Hospital," the meaning is perfectly clear, but it is equally clear that the same words phrased in the way we have first alluded to them are likely to convey the impression that the writer holds three separate offices. We, therefore, sympathise with the complaint uttered by other hospital surgeons, and we deprecate such reduplication of epithets, no matter whether one or many authors are guilty of it.

How Small-pox Spreads.

CONSIDERABLE excitement was recently created in the town of Paterson, New Jersey, says the *British Medical and Surgical Journal*, by the extraordinary conduct of a small-pox patient of the public pest-house. During the absence of the nurses at breakfast, about seven in the morning, he sprang from the window and made his escape, having nothing on but his undershirt. He wandered about the country, meeting with various adventures, and it was several hours before Dr. Hurd, one of the city physicians, succeeded in finding him and getting him in an ambulance. On the way back to the hospital the man jumped from the vehicle and started to run, but was soon recaptured. Scarcely had he been placed in bed, however, before he again jumped from the window, and made off for the mountains. This time he was caught more quickly, and when brought back was tied fast in bed with strips of

sheet torn up for the purpose ; but about two o'clock word was received at the police station that he had a third time escaped, and was running naked through the principal street of the town, followed by about five hundred persons, principally children. Several officers started in pursuit, and he was finally captured in a cellar, from whence he was taken again in the ambulance to the hospital, where he was so securely fastened in bed that further escape was impossible. The health authorities then published a notice to all persons who had come in contact with the man to visit the city physician's office and be vaccinated free of charge.

Hospital Saturday.

MR. SAMPSON GAMGEE, who may claim to have originated the Hospital Saturday movement in Birmingham, lately delivered an address at the Medical Institute in that town on the progress and success which has attended it during the ten years it has now existed. The gross proceeds of the ten collections in Birmingham amounted to £38,681, and inclusive of the district towns, comprising Dudley, West Bromwich, and Wolverhampton, a grand total of £85,610. In London, which had followed the lead of Birmingham, Hospital Saturday has produced in eight years £53,379, thus raising the total of Midlands and London to £115,989. This on the whole will be looked upon as a surprising result, since it has been the means of bringing in a class of persons to take an active interest in the work of hospitals who formerly partook of their advantages and contributed nothing whatever towards their maintenance and support. In Birmingham the Hospital Saturday movement is largely associated with the Provident System of medical relief, and which is both popular and successful. The registration fees of the provident institutions yield an annual income of nearly £1,600 to the medical charities. The working classes, not content with the progress made, are now asking themselves if they cannot set apart a further sum to accomplish some special object, as the building of a new wing to the Queen's, or the Eye Hospital? establish a fund to provide working men whom accident has deprived of their limbs with the best artificial substitutes? baths for the use of the out-patients? or carriages and stretchers for the conveyance of the sick and wounded? To sum up, Mr. Gamgee says: "No one can doubt that a new vein has been struck, if not a new mine discovered, and that, though it may, and probably must remain true, 'that the poor we shall always have with us,' the time is not far distant when a committee (like this at work in Birmingham), one of the most productive of wealth in the whole world, may be relieved of the opprobrium, in plain English, of the disgrace, of having, as now, one in four of its entire population recipients of medical charity."

We are asked to state that at the monthly meeting of the committee of the Zenana and Medical Mission a vote of thanks was passed to Dr. Edmunds, senior member of the staff, and to the London Temperance Hospital Board, for the kind assistance evinced in the way of instruction to the pupils and the opportunities of acquiring practical knowledge.

Homoeopathy and the British Medical Association.

At the last meeting of the Committee of Council of the Association a communication was read from Dr. Rees Philipps, Honorary Secretary to the South-Western Branch, of which the following is a copy:—

1. That this meeting heartily approves of the resolutions relative to homoeopaths, passed at the Plymouth meeting of this Branch, that it regrets that the Committee of Council have not yet seen their way to expel an avowed homoeopath when requested to do so by the unanimous vote of one of the oldest Branches of the Association.

2. That this meeting requests members of the South-Western Branch to help on any movement for obtaining such remodelling of the constitution of the Committee of Council of the Association as shall ensure that the Committee of Council will carry out unhesitatingly resolutions that have been adopted by the Association at its annual meetings.

The only response to these resolutions by the Committee of Council was simply to mark them "read."

Artisans' Dwellings.

We are glad to find that Mr. Shaw Lefevre's Bill for improving the several Acts passed to provide suitable dwellings for the working men of London is likely to become law before the session comes to a close. The Bills of 1875 and 1879 were in many respects unworkable, and too costly, and on the whole did more harm than good by thwarting the operations of the modest measure known as Torrens' Act. The aim of the new Bill is to amalgamate the best and most workable parts of the several schemes proposed and Acts passed to secure homes for those turned out by railways and by the Board of Works in carrying out their street improvements. Sir R. Cross was too ambitious; he proposed that the Metropolitan Board of Works should clear out vast spaces which were mapped out as the haunts of disease. The Board, indeed, made the attempt; but before it had proceeded far, found the cost so enormous that it refused to proceed. A million and a half of money was almost thrown away without obtaining any very appreciable results, providing accommodation for a tenth part of those already displaced and likely to be displaced. It soon became a question of how the Board should grapple with the difficulties of the situation, and if possible keep pace with the rapid growth of the evils with which they had been called upon to deal. To those who had given attention to the question it was evident that Mr. Torrens' Bill was obviously the more statesmanlike, more workable, and far more economical one for dealing with the subject of artisans' dwellings. It provides that the local authorities shall be held responsible for permitting the existence of houses which are unfit for human habitation, and that the rebuilding of houses should rather be left in the hands of individuals than in those of a public board, and those who undertake to build should be compelled to do so properly. No doubt the object will be better and more satisfactorily accomplished in this way than by State interference, or by any Board of Works enterprise, a body a little given to be lavish with the money of the rate-payers.

The State should see that no one is permitted to make profit out of the maintenance and letting of places the sanitary condition of which is such that they must prove

nests of fever or the sources of infectious diseases. It is generally admitted that if the over-crowded, filthy, close, unventilated habitations of the poorer districts of London were cleared out, the rate of mortality, or at all events, the fever-bill of the metropolis, would be reduced very considerably, and many thousands of human beings be rescued from a premature grave.

The Italian Medical Congress.

THE tenth Italian Medical Congress will be held in Modena early next September. It is expected Dr. Bacelli, Minister of Public Instruction, will be present. At the same time as the Congress, there will be held an Exhibition of Hygienic Appliances, and of objects generally connected with sanitary science. In view of the national character of the approaching Congress, the railway and steamboat companies have consented to issue tickets to those who propose to attend at very much reduced rates. All communications should be addressed to the committee, Modena.

The Retirement of Mr. Stone.

It falls to the lot of but few to hold a position of responsibility and to retire therefrom after half a century in the full possession of every mental and physical faculty, as has Mr. T. M. Stone, of the Royal College of Surgeons of England. This gentleman having completed his jubilee as one of the prominent officials of the College, and having elected to retire, it was resolved at a meeting of the Council last week, in testimony of long and faithful service, to allow him a retiring pension of £300 per annum. Those whose business has called them to the College from time to time will be glad to hear of this handsome recognition of services rendered, as they remember with what urbanity of manner and readiness of information and assistance Mr. Stone's long connection with that institution has been characterised, and will wish a continuance of good health to that much-respected veteran in his retirement. It gives us pleasure to learn that there are others outside the College who are anxious to show their appreciation of his services in a substantial manner. To further this object a meeting of Mr. Stone's friends was held at the residence of Mr. Critchett a few days since, when it was proposed by Mr. Luther Holden, F.R.C.S., and seconded by Mr. O. Macnamara, F.R.C.S., "That in consideration of the genial manner in which Mr. T. M. Stone has discharged his duties during the past 50 years' service at the Royal College of Surgeons of England, his numerous friends in all parts of the Globe feel that the occasion of his resignation is an opportunity which they should seize to present him with a testimonial expressive of their warm friendship and deep respect." Sir Erasmus Wilson, F.R.S., was elected treasurer, and Mr. Luther Holden hon. sec. to the fund; and an influential committee was formed to carry out the project.

DR. NEWTON DICKENSON, Demonstrator of Anatomy, and Curator in the Carmichael School of Medicine, has been elected Assistant-Surgeon of the Richmond Hospital, Dublin, in place of Dr. Lentaigue, who was recently appointed Surgeon to Jervis Street Hospital.

A MEETING of Fellows of the Royal College of Surgeons of England will be held in the Assembly Room, Guildhall, Worcester, on Thursday, August 10th, to consider matters affecting the interests of the Fellows generally. The chair will be taken at 1 p.m. by Mr. C. G. Wheelhouse.

DR. JOSEPH ROGERS, President of the Metropolitan Poor-law Medical Officers' Association, asks us to announce that a meeting of this Association will be held in one of the rooms at the Guildhall, Worcester, to-day (Wednesday) at 2 o'clock, to which those interested in Poor-law affairs are specially invited.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Cardiff, Portsmouth, Plymouth 13; Bradford, Wolverhampton 15; Bristol, Derby 16; Edinburgh, Birmingham 17; Manchester, Norwich, Brighton, London, 18; Oldham, Bolton, Halifax, Salford, Dublin 20; Sheffield, Birkenhead, 21; Hull, Leeds, Nottingham, 22; Blackburn, Liverpool 23; Preston, Glasgow, Newcastle-on-Tyne 24; Leicester, Huddersfield 25; Sunderland 28.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 29, Bombay 20, Madras 35; Paris 21; Geneva 14; Brussels 20; Amsterdam 21; Rotterdam 20, The Hague 19; Copenhagen 25; Stockholm 18; Christiania 21; St. Petersburg 44; Berlin 35; Hamburg 24; Dresden 28, Munich 24, Breslau 46, Vienna 27, Prague 30, Budapest, 35, Trieste 30, Rome 25, Naples 35, Turin 24, Venice 30, New York 31, Brooklyn 25, Philadelphia 16, and Baltimore 38. Ill-fated Alexandria was the only principal foreign city from which no returns were received.

IN the report of the proceedings of the Committee of the Council of the British Medical Association we read that communications from the Staffordshire, Bath and Bristol, and South-Western Branches, with resolutions, of which the following is a copy, were presented:—"That in the opinion of this Branch, the *Journal* of the Association should be more fully the medium of record of the transactions of the Branches of the Association than it is, and that the papers read and the records of clinical observation should have precedence of other contributions to the *Journal*; moreover, that they should be more fully reported and be published at an earlier period after communication than has hitherto been done."

THE highest annual death-rates per 1,000 in the large towns last week from diseases of the zymotic class were: From whooping-cough, 1.3 in Liverpool and Sunderland; from measles, 5.6 in Huddersfield; from scarlet fever, 2.0 in Hull; and from "fever," 1.3 in Derby and 1.1 in Newcastle-upon-Tyne. The death-rate from diphtheria showed a further increase upon that recorded in recent weeks; no death was attributed to this cause in Derby or Halifax, whereas its death-rate ranged from 1.1 in the other towns to 4.1 in Sheffield, 4.6 in London, and

5·1 in Leicester. Small-pox caused but 2 deaths in London and its suburban districts, and only 2 in the whole of the provincial towns. There were during the same period but 17 deaths from diphtheria in the United Kingdom.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE CAPPING OF EDINBURGH GRADUATES.—An imposing array of graduates of the Edinburgh University assembled in the Presbyterian Hall on August 1st. to receive the degrees of Doctor of Medicine, Bachelor of Medicine, and Master in Surgery at the hands of the Lord Chancellor (Lord Glenosree). There were thirty-two to receive the M.D. degree, and one hundred and eighty-two the M.B. and C.M. degrees, this being the largest number ever conferred by the University Court at one presentation. Amongst the Gold Medalists we are glad to notice the name of Dr. Halliday Croom, from whose pen an interesting paper "On Atresia Vaginae" appears in another column of the present issue of *The Medical Press*. The dissertation which gained for our contributor this coveted distinction was entitled "Clinical and Experimental Studies from the Royal Maternity Hospital." The other recipients of gold medals were Dr. Bendall, "On Acute Farcy in Man;" Dr. T. P. A. Stuart, "Nickel and Cobalt: their Physiological Action on the Animal Organisation;" and Dr. Albert Wilson, "Clinical Researches with the Sphygmograph." For the first time since its institution, the "Ettles Prize" was divided equally between George Armstrong Atkinson, M.B., and Sydney Johnson Taylor, M.B., they being considered by the Medical Faculty the most distinguished graduates of the year, and equal in point of merit. The Beesey Prize, for distinguished examinations in anatomy, clinical surgery, and surgery, was gained by George Armstrong Atkinson, M.B. and C.M.; the Syme Surgical Fellowship was awarded to Howard Bendall, M.D.; and the Buchanan Scholarship in gynaecology was awarded to David Smart, M.B. and C.M. In another column will be found a complete list of the recipients of degrees before mentioned.

ABERDEEN ROYAL INFIRMARY.—A gratifying mark of the esteem in which the House Surgeon to this Institution, Mr. William Sinclair, is held by the students of his surgical class, was evinced a few days since by the presentation to that gentleman of a handsome case of amputating instruments "in recognition of the care and efficiency with which he conducted the instruction."

VITAL STATISTICS.—From the Registrar-General's returns for the eight principal towns of Scotland for the week ending Saturday, we learn that the death-rate was 21·3 per thousand of estimated population. This rate is 3·1 above that for the corresponding week of last year, but 0·4 below that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 9·0 per thousand; and the highest in Greenock, viz., 31·7 per thousand. The mortality from the seven most familiar zymotic diseases was at the rate of 4·9 per thousand, or 0·2 below the rate for the previous week. Diarrhoea and other bowel complaints were unusually frequent in Glasgow. The other epidemics seem to have been in abeyance. Acute diseases of the chest caused 82 deaths, or 2 more than the number registered during the previous week.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 29th ult., the mortality of Edinburgh was 74, and the death-rate 17 per thousand. Diseases of the chest accounted for 30 deaths, and zymotic causes for 4—of which 1 was due to fever, and 1 to scarlatina.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 29th ult., were at the rate of 25 per thousand per annum, against 22 in the preceding week, and 19, 21, and 18 in the corresponding periods of 1881, 1880, and 1879.

THE NORTH OF SCOTLAND MEDICAL ASSOCIATION.—The annual meeting of this Association was held, a few days since, in the Medical Society's Hall, Aberdeen, Dr. Lyon, Peterculter, the retiring President, in the chair. After the minutes of last meeting had been confirmed Dr. Lyon vacated the chair in favour of the President-elect, Dr. William Pirrie, Professor of Surgery. Dr. Pirrie thanked the members for the great honour they had conferred on him, and assured them he viewed it not only as an honour, but a great pleasure, inasmuch as it afforded him an opportunity of renewing his acquaintance with several gentlemen some of whom he had been related to in the pleasing relation of teacher and pupil. As it had been the custom at former annual gatherings for the President to call the attention of the associated members to some subject of medical or surgical interest, it had occurred to him that perhaps it might not be unprofitable to call the attention of the members now present to the interesting and remarkable investigations that had been made of recent years into the infectiousness of tubercle and tubercular consumption. On this subject Dr. Pirrie delivered an able address, and in bringing his remarks to a close he said the conclusions deducible from the researches made were that persons should avoid receiving into their bodies the breath of consumptives. On the motion of Dr. Beveridge, a cordial vote of thanks was awarded to Professor Pirrie for his address, which he agreed, as suggested by Dr. Beveridge, to have printed and circulated among the members of the Association. Dr. Manson, of Banff, was then nominated President for next year, and the members subsequently dined together.

GLASGOW.—**DR. RUSSELL ON DIARRHOEA AND THE FEEDING OF INFANTS.**—Dr. Russell, Medical Officer of Health for Glasgow, in his last fortnightly report, states that of the 46 deaths from diarrhoeal diseases in Glasgow, there were 40 below five years of age and 6 above fifty, so that not one died of diarrhoea between five and fifty. If we take the average age of the 40 children below five years, we find it was only eight and a-half months. It follows that, practically, this fatal diarrhoea was confined to infancy, and that, therefore, the popular association of summer diarrhoea with summer fruits and vegetables is erroneous. The dangerous diarrhoea of summer is a disease of infancy, and may be explained partly by that improper and careless feeding of children which goes on in Glasgow all the year round among the working classes, and terminates in fatal diarrhoea more speedily in the warm than in the cold months, but still more by the influence of heat upon the milk given to "bottle babies" and weaned children. The facts as to these 40 children are not yet in my possession, but I know from former inquiries that the majority will prove to be "bottle babies," and a large proportion illegitimate.

ANTI-VIVISECTION MEETING AT ABERDEEN.—A meeting was held in Aberdeen on the 31st ult., under the auspices of the Scottish Society for the Suppression of Vivisection. The Rev. Dr. Stewart, Aberdeen, presided. The meeting

was addressed at considerable length by the Rev. Dr. Adamson, Edinburgh, who challenged the efficacy of vivisection as the means of eliciting scientific facts which could not be obtained by other means. He said vivisection had, in some form or other, been practised for two thousand years, and he maintained that it rested with vivisectionists to show that the results they had obtained were, without challenge, the outcome of experiments made on living animals. Dr. Adamson referred at some length to the investigations conducted by Prof. David Ferrier, of London, and stated that men as able, if not more able, than Prof. Ferrier had challenged the deductions drawn by the Professor from his cruel experiments. Dr. Adamson also referred to the experiments of Prof. Rutherford, Edinburgh, now conducted for a considerable number of years, and held that, as in the case of Prof. Ferrier, the results drawn from the experiments were illogical and inconclusive.

Literature.

MEDICAL AND SURGICAL ASPECTS OF IN-KNEE (GENU VALGUM). (a)

IN-KNEE, or knock-knee, a very common affection among the poor and debilitated young residing in crowded and ill-ventilated lanes and alleys of large cities, is seldom seen in rural districts. As regards the pathology and cause of the deformity much difference of opinion exists. Some authorities believe it to be caused by weakness and relaxation of the ligaments of the knee-joint in debilitated young subjects, others again maintaining knock-knee to be produced by a peculiarity of conformation and growth of the internal condyle of the femur; in short, it is attributed by some to a ligamentous derangement of the knee-joint, while others aver it to be caused by an osseous derangement of the articular ends of the bones forming the same joint. We have perused the work before us on the medical and surgical aspects of in-knee (genu valgum) with very great pleasure, as it is from the pen of a distinguished and well-known author on the subject of the deformities of the human frame. Dr. Little, the founder of the Royal Orthopaedic Hospital in London, was the first surgeon of any importance in England who devoted his talent to this branch of surgery. We therefore cannot speak too confidently concerning the information found in the work before us, believing that it is not the ephemeral literary venture of some young and enterprising surgeon lauding some crude and novel operative procedure, but that it is the result of vast experience acquired by a lifelong attention to these subjects.

The volume, which is neatly bound and well printed, contains over 160 pages, is divided into five chapters, and is well illustrated by over fifty figures and diagrams. In Chapter I., treating on in-knee, or knock-knee (genu valgum), and its varieties, at page 2, the author states:—"Many writers have treated of the distortion under two forms—(1) the *Statistical*, in which the influence of gravity has been paramount in its production; and (2) the *Rachitic*, in which softening of bones has been the primary disturbing cause. It is, however, obvious that when rachitic softening has taken place, and the sufferer endeavours to assume the erect posture, and to effect locomotion in that posture, statistical influence will come into operation as well in the rachitic form as in that denominated *statistical par excellence*."

We also find, as mentioned here, "that H. Mayer Volkmann, C. Hueter, and Mikulicz describe two forms of the complaint: that from softening of bones—the *rachitic*, and that which arises from undue augmentation of the work which the knee-joint has to perform when bearing the weight

of the trunk, and especially when carrying heavy loads. The idiopathic, or *statistical*, form: they mostly regard the rachitic form as originating in childhood, and the statistical that which originates in adolescence."

Section II. treats of the pathology and morbid anatomy of the knee and its varieties. Many cases of knock-knee seem to be met with in those who have rapidly "outgrown their strength," having heavy, superincumbent trunks, of necessity borne by weak, attenuated lower limbs, which in turn, sooner or later, exhibit signs of their inability to bear the strain that is placed upon them.

At pages 16 and 17 we find the following interesting statement:—"Hitherto it has been sufficiently noted that there are two periods in the age of man at which growth is extraordinarily rapid. The first period is from birth until the age of nine months; the second period is at the approach of or during puberty or adolescence, say from the tenth or twelfth to the fourteenth or sixteenth year, more or less." . . . "These two periods of most rapid growth are, we venture to say, pre-determined physiologically—the first to hasten the infant's fitness for independent locomotion and self-help to food when the mother's power of lactation may in the normal course be expected to cease, and the infant's absolute dependence on the mother for both locomotion and food shall terminate. The second period is, we consider, allied to sexual development, and the apparent necessity of then more rapidly completing the frame of the individual of either sex to fit it for the propagation of the race, for a life of labour, and its defence against dangers."

At page 34 the author is most anxious to impress upon his readers the importance of distinguishing the difference between the atonic, idiopathic, or infantile non-rachitic in-knee, as well as the same condition of knee produced by rachitis. Section III. is devoted to the consideration, according to the author, of the symptoms and diagnoses of the different varieties of in-knee, such as the atonic, rachitic, spastic, paralytic, strumous, rheumatic. Section IV. comprises the various treatments recommended, and the author believes if the distortion is detected in an early stage much can be done to remedy the evil by a patient and persevering application of simple mechanical splints, coupled with a proper constitutional line of treatment.

Section V. is taken up with the subject of osteotomy, and the various operations devised are described. We agree with the author in thinking that many an aggravated case of knock-knee can be treated successfully without operation, by means of carefully constructed mechanical appliances. Osteotomy is the rage at present for genu valgum, but we anticipate that it will go out of fashion the same way as Sayre's plaster-of-paris jackets did, which were supposed to cure every imaginable form of spinal curvature. In conclusion, we strongly recommend the work to those anxious to acquire a correct idea of the subject.

SARCOMA AND CARCINOMA. (a)

THE basis of the volume before us, the author tells us, is made up of a course of lectures he delivered at the London College of Surgeons, during the years 1880-1881, with numerous notes and additions of new cases to the tables embodied and by sections on diagnosis and treatment. The writer wishes it to be understood that these sections are not intended to be exhaustive treatises on either subject, but are occupied rather with general principles than with minute details, and also to show how largely both diagnosis and treatment are influenced by a more precise knowledge of the pathology of disease, and in the hope of diminishing in a slight degree the reproach which is often made against pathologists of being "unpractical."

In the first chapter the author defines the difference between Sarcoma and Carcinoma, and specifies the different varieties met with, with relation to their microscopic appearance and pathological history.

He states, at page 1: "By *Sarcoma* I understand a tumour of connective tissue origin, composed of elements which are for the most part cellular and embryonic. These elements are embedded in a matrix of inter-cellular substance of varying

(a) "Medical and Surgical Aspects of In-knee (Genu Valgum): its relations to Rickets, its Prevention and its Treatment with and without Surgical Operation." By W. J. Little, M.D., F.R.C.P., late Senior Physician to, and Lecturer on Medicine at, the London Hospital; Visiting Physician to the Infant Orphan Asylum at Wandstead; the Earlwood Asylum for Idiots; Founder of the Royal Orthopaedic Hospital, &c. Assisted by E. Muirhead Little, M.R.C.S. Illustrated by upwards of fifty figures and diagrams. London: Longmans, Green, and Co. 1882.

(a) "Sarcoma and Carcinoma: their Pathology, Diagnosis, and Treatment." By Henry Trentham Butlin, F.R.C.S., Assistant Surgeon and Demonstrator of Surgery and of Diseases of the Throat, St. Bartholomew's Hospital; lately Erasmus Wilson Professor of Pathology, Royal College of Surgeons. Illustrated with four lithographic plates. London: J. and A. Churchill. 1882.

quality and quantity. The vessels run between the cells, and the cells increase in number by division."

He further states by Carcinoma he wishes to be understood a tumour of epithelial origin, possessing generally an alveolar structure. The cells are seldom separated by a visible inter-cellular substance. The vessels run in the walls of the alveoli, not between the cells, and the cells increase in number by endogenous formation.

The work is divided into eight chapters, and the subject-matter is fairly written, and the different deviations of sarcomatous and carcinomatous disease, according to the new microscopical and pathological nomenclature, are distinctly and clearly told.

The source from which the information is derived is drawn out in the tables appended, and evidently the author has taken much trouble in the preparation of these tables, in order that the record of each case reported should be carefully and truthfully given. We therefore must congratulate the writer on the way he has performed his task, and on putting together such a vast amount of facts in such a handy form. Sarcoma and carcinoma, their pathology, diagnosis, and treatment, affecting the testis, sub-periosteal tumours of bone, central tumours of bones, the tongue, the œsophagus, and the tonsil are given in this volume, and the author hopes in a future work to give the same particulars concerning the other organs and structures in the body affected with the same diseases.

DISEASES OF THE EAR. (a)

THE fact of a third edition being required in so short a time testifies to the worth of the book in more certain and forcible language than any review, however long. The economic law of supply and demand receives its best illustration in the case of books. If a book is wanted it is sure to be a success. Mr. Field's book has been a success, but we prophesy for this edition a greater sphere of usefulness than its predecessors. It is no mere compilation of facts; it is a practical, clinical treatise founded on vast clinical experience. The illustrations are excellent and helpful, the text is clear and concise, and the work as a whole is as complete and trustworthy as we could desire. We recommend it strongly to practitioners and students alike.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE EYE. (b)

DR. WILLIAMS' (of Boston, U.S.) smaller treatise on eye diseases is already favourably known to most ophthalmic surgeons. The present work will, therefore, rather be recognised as an extension of his manual than as an essentially new production, since it embodies the riper experience reaped in a wide field of eye practice.

Dr. Williams, as is usual in book-making, takes the several tissues *seriatim*, systematically arranging his subjects for easy reference. The first chapter is occupied with the proper methods of examining the eye and employing the ophthalmoscope, while the more recent modes of determining the anomalies of refraction and accommodation, and their correction by the aid of glasses, are explained and illustrated. Subsequent chapters are occupied with the surgical and medical treatment of eye diseases generally. Commencing with the outer coat and traumatic injuries of the front of the eye, the author proceeds to the inner and more deeply seated affections, and here Dr. Williams is quite at ease, and even more strongly confirmed in his formerly expressed views as to the desirability of resorting to medical treatment in most eye affections. He insists, with Zehender, that "only one fault can be committed in the treatment of iritis, the neglect of the timely use of atropia;" and should the inflammatory action be accompanied by intra-ocular or circum-orbital pain, he would also employ topical applications, and internally, anodynes and bromide of potassium.

With regard to collyria, employed by Dr. Williams in "simple conjunctivitis," we fear they scarcely merit the designation of "mild applications." For our part, we should expect anything but "a cooling refreshing sensation"

(a) "Diseases of the Ear." By George P. Field, Aural Surgeon to St. Mary's Hospital. London: Renshaw. 1882.

(b) "The Diagnosis and Treatment of Diseases of the Eye." By Peary W. Williams. London: Sampson, Low, & Co.

from either his borax or salt lotions. We, however, quite agree in his denunciation of poultices in purulent affections of children. We have always found that the better mode of removing discharges from the eyes of young children is by making a free use of warm water, together with the occasional application of the mildest of astringents. Eye-shields, or guards, are a remnant of the barbarism and ignorance which characterised the nostrums of bygone ages. As to the use of counter-irritants and caustic solutions, these are positively mischievous in most cases. Of glaucoma Dr. Williams says "the cause of the initial condition is still a moot point;" but of the theories propounded he inclines towards that of Donders, who is of opinion that primary the disease is the result of irritation of the ciliary nerves which preside over the vascular supply and the secretion of the vitreous, and whereby the volume of the vitreous is increased. We are not so sure that what he states with regard to the sexes, "that a larger proportion of women than men suffer from glaucoma," must be accepted, or whether it is an established fact that the disease occurs usually "at or after the critical period of life." It may be so in America, but so far as our observation goes, we do not think it is so in this country. With reference to the treatment of glaucomatous affections, Dr. Williams is most decidedly of opinion "that they are never relieved except by operation." This is not in accord with our experience, and we certainly should not have expected the result he obtained in the case of a middle-aged lady "who had been a sufferer for four months, and in whom perception of light was lost, both eyes extremely hard, and prognosis most unfavourable." Nevertheless, on the next day after iridectomy, "she could see every wrinkle in my forehead." We are by no means inclined to look so favourably upon iridectomy, nor regard it as infallible if resorted to in the early stages of the attack; indeed, to do so would be to entirely put aside experience,—ignore medical treatment on all occasions for an operation which, to some extent, may be said to be the fashion of the day. Dr. Williams has no faith either in sclerotomy or division of the ciliary muscle, although he does not deny that the "former is perhaps sometimes useful for the relief of persistent pain when vision is hopelessly lost." The use of myotics, pilocarpine, and eserine as a means of lessening intra-ocular tension have not yet been fully demonstrated. We recommend Dr. Williams to give eserine a more extended trial than he appears to have done. Should pain be persistent, he would resort to enervation, rather than enucleation, as a preferable means of arresting sympathetic inflammation.

Our author's treatment of affections of the nervous tissues—optic nerve, &c.—is based upon sound practical experience and much discrimination, and his division of the several affections of the retina are judicious. We, however, do not quite understand why he should consider it necessary to devote a chapter to the consideration of amaurotic diseases; neither can we accept his statement that the name of amaurosis is retained and generally given to those hopeless states where the optic nerve has become atrophied from cerebral or spinal lesion. We are rather inclined to think that the term amaurosis is retained that Walther's sarcastic observation may still hold good amongst us.

We have said enough to indicate the scope and object of Dr. Williams' book, and we have only further to add that the normal and abnormal changes of the internal eye, as seen by the ophthalmoscope, are accurately represented in two coloured lithographic plates. Specimens of Snelling's test types are also appended. On the whole, Dr. Williams' treatise may be accepted as a practical and trustworthy guide to the treatment of eye diseases.

Correspondence.

THE SPHYGMOGRAPH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your review of Dr. Dudgeon's book on "The Sphygmograph," in your impression of the 12th ult., it is stated, "In our experience the Dudgeon sphygmograph is the easiest worked and most accurate of all these instruments. The pressure gauge shows a range of from one to five ounces troy, and this is a pressure in our opinion quite unnecessary, and beyond what can be usually employed

with advantage." I have tried to point out to Dr. Dudgeon himself that in his instrument, and I believe in others, there is a serious source of fallacy in connection with the wrist-band. I find that on applying the instrument to my own radial, or that of another, I can almost indefinitely modify the character of the tracing by *varying tightness of this band*. What then is the use of the pressure gauge, no matter what its range, if there is *no definite unit of pressure* to begin with? I shall be glad to be enlightened on this matter.

I am, yours, &c.,

D. CAMPBELL BLACK, M.D.

Glasgow, August 2nd, 1882.

ANIMAL VACCINATION OR ARM-TO-ARM VACCINATION?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see it mentioned in your columns that the President of the Local Government Board, Mr. Dodson, on being asked by a member of the House of Commons whether the Vaccination Department recommended the use of animal vaccination in preference to that of humanized, replied that it had no advice to give in this matter.

Perhaps the following evidence may assist some of those who have not seen it to come to some definite conclusion. I find in the Report of the House Committee and Medical Officers of the Small-pox and Vaccination Hospital, Highgate Hill, London, for the half-year ending 30th June, 1881, given me by Mr. Goude, after a discussion on vaccination which I had at the Medical Society of London in November last, the following statistics:—During the six months there were 491 cases of small-pox treated at this hospital, and of these 469 had been vaccinated and 21 were unvaccinated. There was one case of small-pox in an aged man said to have been inoculated in early childhood which proved fatal. The Report goes on to mention that in the unvaccinated cases there were 11 deaths, or about 50 per cent. of all such cases died; and of the 469 vaccinated cases 58 died, i.e., about 1 in 8·5, not a very favourable result.

If I turn now to the evidence for animal vaccination (Prof. Lindsley, of Yale College, on Vaccination, Conn., 1882) I find, p. 14, the following:—"Dr. Meares, health officer of San Francisco, writes in his annual report as follows: 'The bovine virus (Beaugency stock) has been exclusively used by the Health Department since its introduction here five years ago. The vaccinations since that time reach the large number of over 80,000. This is exclusive of the vaccinations performed by the physicians of the city generals. I have yet to see a case of variola or varioloid after a successful vaccination with bovine virus.'"

Dr. Warlomont, in 1878, gave similar evidence, and repeats it in 1881 (*Brit. Med. Journ.*). So does Dr. Henry Martin in his pamphlet. In his remarks before the meeting at Ryde, that gentleman assured his hearers that he had not seen small-pox in any case vaccinated by himself with calf-lymph.

If, then, Sir, this evidence is to be relied on, the only conclusion we can come to is clear: if arm-to-arm vaccination is too weak, or "mitigated," it should be altogether abandoned and replaced by vaccination from the calf.

I am, &c.,

CHARLES R. DRYSDALE, M.D.

London, July 21, 1882.

PASS LISTS.

Royal College of Surgeons of England.—The following candidates having passed the necessary examinations for the diploma were admitted Members of the College at a meeting of the Court of Examiners on July 27th:—

Dawson, George H.	Holcroft, Henry
Dixon, Henry G.	Lynam, Robert G., L.S.A.
Downman, Charles F.	Northcot, Arthur, L.S.A.
Dutton, Wm. H., M.F. Edin.	Perez, George E., L.S.A.
Faunce, Charles E., L.S.A.	Williams, J. A., M.B. Aberd.
Wise, Charles H., L.S.A.	

The following were admitted Members on July 28th:—

Beattie, Robert, M.D. Q.U.I.	Leadbeater, Thos. E., L.S.A.
Berry, John B., L.S.A.	Morse, Thomas R., L.S.A.
Bostock, John, L.S.A.	Pollock, George S.
Harris, Walter T., L.S.A.	Rogers, Thomas E., L.S.A.
Hoyland Stanley S., L.S.A.	Salmos, Arthur G., L.S.A.

The following were admitted Members on July 29th:—

Bevor, Hugh R., L.S.A.	Hudson, Ernest, L.S.A.
Bott, Joseph, L.S.A.	Lovegrove, Thomas E., L.S.A.
Cox, F. R., L.R.C.P. Lond.	Roe, A. D., B.A., M.B. Cantab.
Durant, R. J., L.R.C.P. Lond.	Tate, Alan E., L.S.A.
Howard, R. J. B., M.D. McGill	Voss, Francis H. V., L.S.A.
Williams, Evan, L.R.C.P. Lond.	

The following were admitted Members on August 1st:—

Finch, Thomas, B.A. Cantab.	Jones, Owen C., L.S.A.
Thomas, John H., L.S.A.	

Out of the 280 candidates examined, no fewer than 118 were rejected, and 38 passed in Surgery, and qualified in Medicine will be admitted members of the College.

University of London.—The following is the pass list for the 1882 Preliminary Scientific (M.B.) Examination—not concluded:—

First Division.

A'ams, Charles Edward	Joly, Antoine Maurice
Albop, Chas. Fredk. Manning	Leung, Alfred William
Balgarnie, Wilfred	Legg, Walter Littlewood
Basu, Jagadiah Chunder, B.A.	Macdonald, Isabella Macdonald
Bidwell, Leonard Arthur	Macevoy, Henry John
Blackler, Henry John	Mey, William Page
Blackston, Charles Reginald	Padgen, Trayton Charles
Brennan, Joseph Richard	Permewan, William
Brock, Ernest Henry	Redfern, John Joseph
Brook, William Henry Breffit	Roper, Harold Kennaway
Brown, Arthur Edward	Sansom, Harry Arthur
Cameron, Robert Watson	Seville, Charles Frederick
Canney, Henry Edward Leigh	Shirliff, Edward Dickinson
Carnegie, Douglas John	Simpson, Charles Shackleton
Clarke, James Jackson	Smith, Alexander Rochfort
Clarke, William Frederick	Smith, Hugh
Cook, Samuel Bird	Solly, Ernest
Cox, Alfred Edward	Stery, John Herbert
Crook, Herbert Evelyn	Stephens, Richard John
Davies, Ernest Bent r	Thompson, James Edwin
Dewhurst, John Henry	Tomlinson, William Henry
Edge, Frederick	Toogood, Frederick Sherman
Elliot, William Henry Wilton	Tunstall, John Ogle
Evans, Isabel Clare	Wheaton, Samuel Walton
Gilchrist, Thomas Caspar	Wheeler, James Atkin
Harper, William Norton	Wilkinson, Percy John
Helsham, Hugh Paul	Wray, Richard Spalding
Jecks, Cyril William	

Second Division.

Anstle, William Charles	Kelson, William Henry
Aveline, Henry Talbot Sidrey	Kingsford, Edward Clau
Barker, George Henry	Lang, Arthur Joseph
Biddlecombe, Edward Henry	Legg, Cyrus
Bidwell, Lawrence	Lindor, Albert
Brown, Arthur Thomas	Lys, Henry Grabham
Burghard, Frédéric François	Marshall, Charles Frederic
Burns, James	Moore, Robert Lee
Burrell, Arthur William	O'Reilly, George Hartley
Carter, Weldon Cragg	Paltridge, Mary Elizabeth
Conolly, Charles Hamilton	Pickering, Rowand Neville
Coryn, Herbert Alfred William	Umfreville
Craig, Henry Edward	Prall, Samuel Edmund
Crouch, Charles Percival	Pugh, John Williamson
Davidson, Harold	Randall, Ernest Biddood
Davis, Arthur Holdsworth	Ridson, William Newt
Dean, Henry Percy	Roberts, David Foulkes
Dobson, Leonard Chas. Talbot	Scott, Arnold
Duncan, Charles Herbert	Shadwell, Bertrand
Featherstone, Wm. Bartrop	Smith, Edmund Fauriel
Fisher, Theodore	Smith, Henry Ernest Hill
Freeman, Ernest Carrick	Smith, John Anderson
Furnival, Bryan	Smith, Robert Gillies
Godfrey, Albert Edward	Sprent, Frank Arthur
Halliwel, Thomas	Stedman, Frederick Edmund
Hammersley, Percy H. Vickers	Stokes, William Percy
Haring, Nathan Charles	Stokes, Frederick William
Harris, Frances	Swayne, Walter Charles
Hensley, Arthur Egerton	Walls, William Kay
Holloway, Samuel Frederick	Wethered, Frank Joseph
Joseph, Arthur Hill	Whitcombe, William Sandford
Kanthack, Alfredo Antunes	Williams, Frederic Newton
Kell, Edmund Delacourt	Wynter, Andrew Ellis

University of Edinburgh.—The following is a list of candidates on whom the degree of Doctor of Medicine and the degrees of Bachelor of Medicine and Master in Surgery were conferred:—

The Degree of Doctor of Medicine.

Barr, A. George, M.B. and C.M.	MacLennan, D. U., M.B. and C.M.
Bendall, Howard, M.B.	Macphail, S. R., M.B. and C.M.
Brebnner, C. Reith, M.B. and C.M.	Mead, E. W., M.B. and C.M.
Cameron, R. W. D., M.B. and C.M.	Oakes, A. W., M.B. and C.M.
Chisholm, J. M. D., M.B. and C.M.	Oliphant, W. B., M.B. and C.M.
Croom, John H., M.B. and C.M.	Renton, James Crawford
Druitt, Lionel, M.B. and C.M.	Ross, Joseph C., M.B. and C.M.
Furley, William Grant, M.B.	Shaw, William, M.B. and C.M.
Guillemard, B. J., M.B. and C.M.	Smith, George D., M.B. and C.M.
Handford, Henry, M.B. and C.M.	Stuart T. P. A., M.B. and C.M.
Hope, E. William, M.B. and C.M.	Taylor, H. C., M.B. and C.M.
Hutchinson, E. de W., M.B. and C.M.	Thom, Alexander, M.B. and C.M.
Leeson, John Rudd, M.B. and C.M.	Thomson, James, M.B. and C.M.
Le Fèvre, George, M.B. and C.M.	Tunstall, A. C., M.B. and C.M.
Mackenzie, J., M.B. and C.M.	Watson, C. S., M.B. and C.M.
McLean, O. E., M.B. and C.M.	Wilson, Albert, M.B. and C.M.

The Degree of Bachelor of Medicine and of Master in Surgery.

Aitchison, Robert Swan
Aitchison, Thomas
Archer, Leonard T. Fitz-Samuel
Ashdown, Herbert Harding
Aswell, Frederick
Atkinson, George Armstrong
Baily, Thomas Ridley
Baillie, Peter
Baird, M. Manook (M.A. Calcutta)
Bain, Basanta Kumar
Ball, George James Hamilton
Ball, Horace Lynden
Benjafield, William Barnett
Belton, Joseph Shepherd
Bond, John Henry Richard
Borrowman, Philip Grierson
Boswell, Henry St. George
Bourne, C. H. (B.A. Durham)
Bowie, John
Bowman, A. S. (B.A. Sydney)

The Degree of Master in Surgery.—Howard Bendall, M.D.

Royal College of Surgeons, Edinburgh.—The following candidates having passed the required examinations, were admitted Licentiates of the College:—

Carruthers, John
Daniell, David Hugo
Donald, David
Duncan, John George

Fennell, Edward Cooper
Haworth, Frederic George
Healop, Frederick Albert
Steele, Elmes.

The following candidates having passed their final examination for the Licence in Dental Surgery, were admitted L.D.S.:—

Laane, George John

Monroe, David.

Royal Colleges of Physicians and Surgeons, Edinburgh.

—The following candidates having passed the necessary examinations during the July sittings of the Examiners, were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh during July and August:—

Anderson, John
Belton, Cassius W.
Berry, John J.
Blackwell, Frederick W.
Brenner, Alexander McRae
Broome, David McMahon
Brown, William James
Buckley, Cornelius
Caldwell, James A.
Carruthers, Robert Buck
Chadwick, George Frederick
Delaney, James William
Devlin, Thomas Patterson
D'Gruyther, Eustace J.
Dickson, Winton
Ebell, John Henry
Ellis, Edward
Finlay, John T.
Flood, William
Gee, Thomas E.
Graham, John Saunders
Graham, Joseph
Hadden, William James
Holmes, Joseph
Horder, Edward George
Kemble, Arthur Charles

King, John C.
Legat, Henry Thomas
Main, Robert
McBride, John
Menzies, James
Moloney, Patrick O'Donnell
Neale, George
Nockolds, William Stephen
Ottmann, Adolphe W.
Panist, John Emanuel

Rodgers, James Henry
Rowan, Stephen F.
Salter, Francis Joseph
Scott, Harry
Simpson, Edwin
Sinclair, George
Swallow, Francis McDonald
Taylor, George H.
Todd, Andrew Thomas
Wallace, Robert Richard
Waburton, James
Watson, James
Wilson, Gerald Barry

Wilson, James Patrick A.

Army Medical Service.—The following is a list of surgeons on probation in the Medical Department of the British Army who were successful at both the London and Netley examinations, arranged in the order of merit:—

(a)	Marks.	(b)	Marks.
S. Westcott	2,295	H. S. McGill	2,005
B. H. Whitehead ..	2,280	A. A. Fecheil	2,060
B. M. Skinner	2,200	C. R. Tyrrell	2,020
C. B. Bartlett	2,195	J. Hickman	1,980
J. D. T. Beckett ..	2,175	W. B. Thomson	1,975
T. A. P. Marsh	2,160	H. E. Deane	1,945
B. Kirkpatrick	2,140	S. O. Stuart	1,940
A. C. A. Alexander ..	2,095		

(a) Gained the Montefiore Medal.

(b) Gained the Martin Memorial Gold Medal.

Indian Medical Service.—The following is a list of surgeons on probation in Her Majesty's Indian Medical Service who were successful at both the London and Netley examinations, arranged in the order of merit:—

(a)	Marks.	(b)	Marks.
H. H. R. Charles ..	5,455	J. P. Barry	4,852
G. Duncan	5,025	A. V. Anderson	4,497
W. A. Sykes	4,875	E. W. Bailly	4,415
B. W. S. Lyons	4,860	J. Scott	4,150

(a) Gained the Herbert Prize, the Parkes Memorial Bronze Medal, and the Montefiore Second Prize.

(b) Gained the Prize in Pathology.

IRISH POOR-LAW SUPERANNUATION.

THE Select Committee for consideration of this Bill was nominated on Saturday last, notwithstanding the opposition of Mr. Biggar, who not only resisted progress, but made an effort to exclude Mr. Meldon from the Committee because he supposed that gentleman to be favourable to medical claims. When Mr. Biggar divided the House, he found himself the only voter in his own lobby, of which any one but the honourable (1) gentleman would be heartily ashamed. The Committee will sit at once, and probably take evidence on Wednesday (to-day) and Thursday.

Mr. Collins, whose name was at first proposed, was not nominated, but in his stead Mr. Daly, who we believe to be an enemy of the Union officers, was appointed.

The Committee consists of the following members:—The Attorney-General for Ireland, Messrs. Healy, Justin McCarthy, Meldon, Gibson, Fitzpatrick, Aylmer, Biggar, Sir P. O'Brien, Herbert Gladstone, Colonel Tottenham, Mulholland, Callan, Greer, Findlater, and Daly.

The London Hospital.—The following is a list of the prizes presented by H.R.H. the Duke of Cambridge, K.G., president of the hospital, on July 18th:—Students' Prizes: Entrance Science Scholarship, £60, Mr. F. J. Smith; Buxton Scholar-

ships, £30, Mr. W. R. Hodge, £20, Mr. J. W. Pugh; Lethby Prize, £30, Mr. A. J. Richardson; Scholarship in Anatomy, Physiology, and Chemistry, £25, Mr. F. Hichens; Scholarship in Human Anatomy, £20, Mr. H. Cropley; Scholarship in Clinical Medicine, £20, Mr. R. F. Fox; Scholarship in Clinical Surgery, £20, Mr. R. F. Eox; Scholarship in Clinical Obstetrics, £20, Mr. A. J. Richardson, Hon. Certificate and £12, Mr. R. F. Fox; Minor Surgery Prizes, Messrs. J. M. Evans, J. E. Crisp, J. Thomas, F. Hichens; Dissection Prizes, 1st, Mr. H. Jaboor, Jun., Mr. H. Jaboor, Sen.; Osteology Prizes, 1st, Mr. J. Vincent, 2nd, Mr. C. T. Samman. Prizes to Nurses: The following were awarded for the first time, as an encouragement for proficiency in nursing among the probationers: 1st Prize, £5 5s., May Russell; 2nd Prize, £4 4s., Helena Greaves; 3rd Prize, £3 3s., Ada Moore.

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. SIDNEY DAVIES.—Communication received too late for present issue.

NEMO.—We are not aware that any list of medical appointments is obtainable for the Colonies or the Emigration Service. Information relative to employment in either branch can only be had on written application to the Colonial Office, London, and the Government Commissioners of Emigration. In the former case we fear our correspondent will stand but a poor chance, as there are at least a hundred applicants for every good Colonial appointment.

DR. W. J. BLACK (Hanover).—Thanks. We will look through the M.S., which at first sight appears interesting.

DR. R. P. (Exeter).—In reply to a question in the House of Commons on Monday last, it was stated that "if time permitted the Report would be presented." We fear the same reply has been given in a large number of cases, and that "Lunacy," like other matters, will be amongst the slaughtered innocents.

RUSTICUS.—Your request is a most curious one: we cannot very well comply with it unless we forego that which it is necessary we should observe strictly. The circumstances, however, are so peculiar that, on receiving all the particulars, we will consider whether it may not be possible to accede to the proposition.

MR. M'JAMES.—Tonga has been successfully employed in a great number of cases for the relief of neuralgia attacking the cranial nerves. Dr. Wallace, of Newark, New Jersey, has very recently testified to its excellence as a remedy in these cases, and especially insists on its value as producing no toxic effects, it may be used in all cases with safety. It will not, of course, always succeed, any more than any other drug employed to relieve pain; but it is decidedly worthy of trial where other things have failed. Any respectable chemist will obtain it.

THE LUNATIC.—The case is one for treatment in a private lunatic asylum. The rates charged vary with the accommodation required. You may rest absolutely assured that the best interests of the patient will be alone consulted in such an institution.

DR. W.—Let the matter stand over for a while. It will not be long ere a meeting of the Society will be held again, when you can lay the facts of the case before it, and be guided by the suggestions made you.

DR. GUY H. H.—We do not see our way at present to publishing such a series, but if you will refer to it again a few months later on the matter shall be fully discussed. It is one on which the full staff should be consulted, and this could not be done just now. The case is a notable one.

MIDWIVES AND UNQUALIFIED ASSISTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I read with much interest the article in your issue of July 26th on "Midwives," and having been in active practice for upwards of forty years in the provinces, it has fallen to my lot during that time to witness some most fearful cases of death from post-partum hemorrhage, or permanent injury done from the ignorance and officiousness of that class. To appear clever, they often drag away at everything within their reach as soon as possible, with the utmost indifference to the after-consequences from inertia uteri, adherent placentas, distention, mental emotion from an excited state of the circulation, and many other causes of mischief, which their anxiety to do without medical men have entailed upon their hapless victims. To deal with ignorant midwives and the swarm of unqualified assistants, you have indeed set yourself an uphill task. These latter are to be found in every large town practising on their own account after they have been dismissed from the service of some general practitioner. But I have often observed that, when left to their own unaided resources, they were equally as dangerous as the midwives; yet these two are quite ready to take the field against the regularly qualified and registered practitioner, as there seems to be no legal power at present to prevent them doing so with impunity: and it is only when they are likely to get into trouble that they suggest to the patient or friends that they had better call in the aid of another medical man to assist them. It was only last week that I was hastily summoned to a case of convulsions, after delivery, that had been attended by one of these unqualified assistants, with whom, I need scarcely say, I declined

seeing the patient, and told the people that, as he was not a medical man at all, I should refuse having anything to do in the case unless he was discharged. The promise of attendance for half the regular fee is, no doubt, the great inducement among the poor to their employment; and as their education has cost little, they can the better afford to do so. The fault began from the ignorance of the public, and from the negligence of the profession in having first engaged unqualified assistants, so that at this time, unless some relief or more stringent regulations can be enforced by the Government, we shall go from bad to worse.

Yours very truly,

Falsgrave, Scarborough.

THOS. T. PETERSON, M.D.

Vacancies.

Belmullet Union, Knocknallower Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, August 14.
Cancer Hospital, Brompton.—House Surgeon and Registrar. Salary, 75 guineas, with board, &c. Applications to the Chairman, at the offices, 165 Piccadilly, London, W. (See Advt.)
Chichester Infirmary.—House Surgeon and Secretary. Salary £80, with board. Applications to the Secretary before September 9th.
Earlswood Asylum.—Medical Superintendent. Salary, £400, with extras. Applications, endorsed "Medical Superintendent," to be sent to the Secretary, 33 King William Street, London, E.C., before August 21st.
North Stafford Infirmary.—House Physician. Salary commencing at £100, with board. Applications to the Secretary, at Hartshill, Stoke-on-Trent, before August 23.
Salford Infirmary.—House Surgeon. Salary, £100 per annum, with board. Applications to the Secretary before August 25th.

Appointments.

BARNES, R., M.D., F.R.C.P., an Honorary Consulting Physician to the Chelsea Hospital for Women.
BERRY, G. A., M.B., C.M., F.R.S.E., Assistant Ophthalmic Surgeon to the Royal Infirmary, Edinburgh.
BOUCHER, A. H., M.D. Edin., House Surgeon to the East Suffolk Hospital, Ipswich.
CAMPBELL, P. E., M.B., C.M., Senior Assistant Medical Officer to the Metropolitan District Asylum, Caterham.
CRALLAN, G. E. J., B.A. Cantab., M.B.C.S., Assistant Medical Officer to the County Lunatic Asylum, Cambridge.
ERWIN, S. J., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Openshaw District of the Chorlton Union.
HATTON, G. S., M.D., M.S. Dur., M.B.C.S., House Surgeon to the North Staffordshire Infirmary.
MOULLEN, C. W. M., M.D. Oxon., F.R.C.S. Eng., Junior Assistant Surgeon to the London Hospital.
SMALLMAN, B. F., M.B.C.S., Medical Officer for the Sutterton District of the Boston Union.
SPACKMAN, H. E., L.R.C.P. Lond., M.B.C.S., House Physician to the Wolverhampton and Staffordshire Hospital.
SPENCE, W. J., L.R.C.P., L.R.C.S., House Physician to the Bradford Infirmary, vice Mr. Foster, resigned.

Births.

CRAWFORD.—August 3rd, at St. John's Park, Blackheath, the wife of Dr. Crawford, Director-General Army Medical Department, of a son.
HALL-MORE.—August 3rd, at Walmer, Kent, the wife of Robert Hall-More, M.D., Staff Surgeon, Royal Navy, of a son.
PURVES.—August 2nd, at 10 Stratford Place, Oxford Street, London, the wife of W. Laidlaw Purves, M.D., of a daughter.

Marriages.

BEESTON.—READ.—August 4th, at Dublin, Joseph Lieveley Beeston, L.K.Q.C.P., and L.R.C.S.I., to Anna Maria, youngest daughter of William Read, Esq., solicitor.
CORTIS.—BRUCE.—August 3rd, at St. Mark's, Kennington, H. Liddell Cortis, M.B.C.S., to Mary, daughter of J. Bruce, Esq., of Stockwell.

Deaths.

ADAMS.—July 29th, at Queenstown, Andrew Leith Adams, LL.D., F.R.S., Deputy Surgeon-General Army Medical Department, Professor of Natural History, Queen's College, Cork.
JOHNSTON.—July 29th, at Glasgow, John Reid Johnston, M.D., aged 24.
LUBBOCK.—August 1st, [at St. Leonards-on-Sea, Lora, the wife of Montagu Lubbock, M.D., of 19 Grosvenor Street, London, aged 35.
MC EWEN.—August 1st, at 21 Nicholas Street, Chester, Wm. McEwen, M.D., M.B.C.P. Lond., F.R.C.S. Ed., J.P. for Chester.
HOPKINS.—August 1st, at Highbury New Park, N., Alfred Boyd Hopkins, M.B.C.S., aged 48.
HURST.—July 29th, at St. Mary's Square, Kennington, William Hurst, M.B.C.S., aged 56.
MALE.—July 29th, at Yeovil, Henry D. Male, M.D. Brus., L.R.C.P. Lond., of Victoria Park Square, London.
PEPLOW.—July 27th, at Lower Tooting, Surrey, Joseph Peplow, M.D., L.R.C.P., late of Great Russell Street, W.C., aged 76.
POULTON.—July 31st, at 52 Elgin Crescent, Notting Hill, W., Deputy Surgeon-General C. W. Poulton, M.D., aged 59.
SAYER.—July 30th, at Kenninghall, Norfolk, Thomas John Sayer, Surgeon, aged 56.
SMITH.—July 31st, at the Paddington Provident Dispensary, William Smith, M.B.C.S., for 42 years House Surgeon to the Institution, aged 71.

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE V.—(Concluded).

WE have now to consider the laws just adverted to in relation to those which regulate the recurrence of inflammatory attacks. That certain forms of erysipelas are prone to become persistently recurrent is, as I have already observed, well known. We habitually recognise the fact that a patient is liable to erysipelas, and expect that in him attacks will be produced by slight causes that will prove of much less severity than first ones usually do. If the recurrence has been very frequent the attacks are usually very short and mild; sometimes the intervals are so short that the disease becomes almost persistent. Exactly the same facts are observed as regards proclivity to catarrh in all its varieties. They are sometimes also seen in liability to repeated attacks of diphtheria, a fact which has been recognised by many writers. I had recently occasion to perform tracheotomy in an orphan school on a child who was in *extremis* from croup. In conclusive proof of the nature of the disease we removed at the time a large fibrinous cast of the trachea. The child passed through, I was informed, four attacks of croup previously. It recovered after the operation, and has, I believe, since been threatened with a sixth attack, which, however, never became severe. There is a peculiar form of oedema of the eyelids and cheeks which is caused by repeated attacks of erysipelatous inflammation, and which results at last in permanent deformity. Of this I have seen many examples. In these cases the first attack is usually one of the ordinary form of erysipelas of the face, with the liability to indefinite extension constantly witnessed in the malady,

but the later ones are limited both in duration and extent, and the patient at length comes to know what to expect, and to be confident that the swelling will not go further than the face, nor last longer than a week or ten days. In some persons, and especially, I think, in the young, the upper lip and the alæ nasi are affected rather than the eyelids. The type of inflammatory action sometimes, as may be inferred from what I have said, ceases to be the most characteristic of erysipelas, and in others from the beginning it has in minor features departed from the type. Thus there is a form which we might call vesicating erythema which often affects the cheeks symmetrically, is of limited duration, and occurs over and over again. In some instances the vesication is extremely slight, and possibly absent, and erythema with cedema is all that we see. The cases differ from erysipelas in that there is little or no tendency to spread at the edge, and in some instances, in the comparative absence of cedema. They occur, I think, chiefly to the young, but adults and elderly persons are liable to recurrent inflammatory attacks of parallel clinical history in which the type of disease is rather of an acute but transitory eczema. All those diseases appear to be for the most part catarrhal in origin, that is, the exciting cause is usually exposure to wind or cold. They are of great interest to us as proof that maladies which are probably due to very similar causes both predisposing and exciting, may yet be attended by differing outward manifestations, and that when once the type has been taken in the individual the recurrences will be all of the same character. They also form interesting pathological links one with another, and between erysipelas and its allies. The morbid conditions which I have been referring to certainly establish in the individual who is their subject, through their long persistence or frequent recurrence, a state of health well deserving the name of diathesis, and there can be little doubt that the peculiarity so produced might and would be likely to become hereditary. We thus have occasion to note how a permanent and transmissible peculiarity of health may take its origin. Erysipelas has in elephantiasis a congener of great interest. The distinction between the solid cedema which results from recurrent attacks of erysipelas and the more characteristic form of elephantiasis is only a matter of degree, and it is well known as regards all elephantiasis that repeated attacks of rigors with erysipelatous swelling are constant features of the disease. One is tempted, indeed, to go the whole length, and declare that elephantiasis is, after all, only an example of persisting exceeding chronic erysipelatous inflammation with its resulting hypertrophic

changes. Elephantiasis may vary infinitely in degree, but not at all so far as I know it in kind. It always begins in cedema, and from this it slowly progresses to hypertrophy. The hypertrophy may implicate the corium and cellular tissue only ("smooth elephantiasis"), or it may involve also the papillæ, and produce the tubercular form. Usually these two forms occur together in different parts of the same limb. The solid cedema, which is its first stage, may begin from a variety of causes. It may be induced by an attack of *bona fide* erysipelas, by an injury, by any slight local inflammation, a chancre, an excoriation between the toes, &c., &c. Almost invariably its persistence is favoured by the mechanical disabilities of the part as regards the return of the venous blood and the contents of the lymphatics. We meet with elephantiasis chiefly in the legs, the labia, clitoris, penis, and scrotum, parts which, if once they become swollen, are dependent. The non-symmetry which prevails in a large majority of cases denotes the influence which purely local inflammation has in locating the disease. In some cases it affects equally both legs, and in these it may be taken for granted that the constitutional predisposing cause is strong. Such cases prove the fact of hereditary diathesis. They are scarcely ever met with in England, but only in those climates where the disease is endemic, and in races or tribes who are peculiarly liable to it. When the elephantoid process has once well set in I believe it is never wholly cured, and no better instance could be produced of the pathological advantages of possession. The worse the disease is the worse it is likely to become. It is emphatically a self-aggravating malady. The mere fact of its existence tends necessarily to its spread. Slowly but surely it undermines the health of its subject, impoverishing his blood, and mainly by the recurring attacks of erysipelas which attend it, enfeebling his tone. Constitutional treatment does but little, and local measures are the only chance of benefit.

We need not feel much difficulty in interpreting the phenomena which we witness both in recurring erysipelas and persisting elephantiasis. They are doubtless examples of the pathological power of habit and indulgence. Just as a man who has once yielded to intemperance is in danger of becoming a drunkard, so it is with the tissues. The oftener they have yielded to any special process of inflammation, the more prone are they to yield again. No doubt but that as in the case of the drunkard and the epileptic, so also here pre-existing susceptibility takes its share in favouring both the first outbreak and the continuance. This share, however, probably varies much in different cases, and may in some have been but very small. The main power at work has doubtless been the increase of proclivity which every recurring attack begets, until at length the habit or the disease, call it which we will, becomes fixed. Nor must we consider, as I have already remarked, that this power of habit will be restricted in its influence to the individual. If children be born to a man after the habit has been acquired, they will almost necessarily inherit it. The certainty of inheritance will be in ratio with the fixity of the habit and the length of time that it has persisted before the birth of offspring. A great difference must be noted as the inheritance of proclivities which are developed before and after the conception of offspring. If a disease comes into active existence only subsequently to the production of the whole of the offspring of its subject, clearly the latter will inherit only the degree of proclivity; and it may chance to have been but very small which their parent may have originally possessed; but if born after the diseased process has been long in activity, they will take over the original disease much augmented under the force of pathological habit. Illustrations of this in the case of the children of drunkards are of common occurrence. It is all the difference there is between one who simply bequeaths his patrimony as he received it and one who has largely increased it by his own gains. Elephantiasis, although preceding the same disease, whether met with in temperate climates or in the tropics, is far more common and severe in dark races and hot countries. Malaria has, perhaps, something to do in predisposing to it, and heat and moisture unquestionably aggravate it. It is, possible, however, that we have much aggravated our impressions both as to race and climate as strong influences, since the laws of inheritance will account for excessive prevalence to a large extent when once it has obtained its hold. It may be that we should regard it as to a considerable extent resulting from a diathesis which is heritable in certain families, tribes, and races. There are certain phenomena which may, perhaps, deserve the name

of revealing symptoms. Not but that all symptoms are in a sense revealing, but there is a special and emphatic manner, since they disclose the fact of the existence of a tendency which, although present from birth, possibly has never been suspected. Symptoms of this kind occur, as might be expected, in connection with powerful exciting causes. Peculiar manifestations following the employment of special drugs, or in the introduction of special animal poisons, may rank under this head. If a patient who receives the virus of small-pox develops a hæmorrhagic eruption, or if acne follows small doses of iodide of potassium, we may feel sure that in these occurrences we have a revelation as to the peculiar idiosyncrasies of the individual. It is certain that those to whom these events happen differ, and have probably differed through the whole of life, from others in whom similar causes are not followed by similar effects. The touchstone by which these individuals' peculiarities may chance to be revealed are innumerable. The behaviour of the vaccination sore and that of the primary sore often furnish to the observer an unexpected clue to the peculiarities of the individual. Sometimes the revelation concerns only the specific cause which has been in action, but in others it extends much more widely. For instance, I believe that a clean well-indurated chancre without tendency to ulcerate or inflame rarely occurs, excepting to a person in sound health, and is far more common to those of dark complexion than in the fair. An opposite tendency on the part of the sore by no means always reveals or implies weak tissues or poor health, but it often does so in a definite manner. In making inferences of this kind, however, we must guard against the error of attaching importance to the state of the sore during the first week, which is usually due rather to peculiarities in the pus in which the contagion was effected than to those of the recipient. The syphilitic virus itself is, on the other hand, always probably the same, and differences in its results are due to temperament, diathesis, or health state of its recipient, and come into the class of revealing symptoms. Some of these phenomena deserve, I think, another distinctive name, and may be conveniently known as retrospective symptoms. They reveal not that which is to come, nor even that which is present, but rather that which is past. In some cases it may be their causes are still extant and influential, but in many I believe that the symptoms in question occur only at a considerable period after the termination of the activity of the influence which gave it birth, and that they imply little or nothing as to the present health of the patient or his future liabilities. They may, however, reveal a diathetic tendency, which by hereditary transmission may bud out anew in offspring. The explanation of this probably is that they are associated with diatheses which manifest their existence chiefly in middle or early periods of life. The term, *retrospective symptoms*, ought not, perhaps, to be applied to conditions which are simply the remains of bygone disease, however useful in a little way such conditions may be. It is rather to be kept for conditions which originate late, and which, like slow-growing seeds, spring up long after the seed time. The best example which I can give of what I mean occurs in the instance of xanthelasma palpebrarum. When xanthelasma is developed in various parts of the body in an adult, I believe it is always associated with liver disease, and often with definite and severe jaundice. In these instances it reveals a still extant hepatic diathesis, plus probably some slight tendency to new growth and fatty degeneration. In the far commoner cases, however, in which xanthelasma patches are met with in the eyelids—only no such association is observed—a large majority of those who show them have never had jaundice, and are in no sort of danger of it. Many, however, have in former years suffered much from bilious headaches, and if not actually from these, they have experienced repeated temporary health-disturbances, attended by dark areolæ around the eyes. It is this fact which the patches in question reveal, and they may occur for the first time long after all liability to the disturbances in question have ceased. They are, therefore, retrospective, and I am inclined to think that in many cases they are solely so, and that little or nothing is to be inferred from them as to the patient's future. In other cases—and perhaps not a very small minority—the original liability still persists, and will continue to show its effects. But even in these xanthelasma patches are usually the product of what is long past, and have required a very long time for their reproduction. 1

have already spoken of certain other and very rare cases in which xanthelasma occurs in young children—possibly in several members of the same family—always in a multiplex form, and without any association with disturbed health. In these curious cases I would suggest that the retrospective is yet further back, and that they reveal the fact that some predecessor has suffered from liver disorder, or possibly been the subject of xanthelasma itself. It is true of a number of morbid states which have received special names, and are often spoken of as if they were complete in themselves and distinct from all others, that their chief interest for the nosologist lies in the fact that they are symptomatic of diathesis. Their occurrence reveals the states of peculiar health into which the persons showing them have respectively fallen. Thus, as we remarked when dealing with the subject, enlargement of the thyroid gland, when endemic, reveals a diathesis which may end in great degradation of the physical state generally, and we ought by no means to be content to name it bronchocele, as if in that term we had denoted the whole malady. I propose now to take up in succession a number of names, and separate according to custom distinct diseases, and to ask concerning each what is its symptomatic value, what does its occurrence reveal, how far may its existence help us to the discovery or recognition of the health peculiarities of the individual. We will take first acne. Under this name certain conditions which differ considerably from each other are grouped, but my impression is that the grouping is to a considerable extent natural, and that they really are closely related. All forms of acne have this in common, and they are due to morbid processes occurring in or around sebaceous glands, and further, that their commonest site is the face, with the exception, perhaps, of white acne of milium, which is due to congenital occlusion of some of the gland orifices and accumulation of white albumen (?) under a thin transparent pellicle of epidermis. All are, at one stage or another, attended by congestion or inflammation. Their differences depend probably upon differences in the character of the skin in different persons, differences in age, and modification in the ordinary cases. In order that acne should occur, it is essential in the first place that the sebaceous system should be largely developed, and the skin moderately thick. These conditions given, we shall then be able to watch the play of various influences, local and general, upon their subject's health in producing its various forms. If his state of tone and vigour remain perfect, probably his glands will continue to elaborate and pour forth their secretion without any disturbance. No accumulation will occur, and no secondary congestion around them will be observed. But the slightest, the most temporary disturbance of tone may derange the function of these glands, and may permit the retention of a thick secretion, or favour the occurrence of inflammation around an irritating plug. How rarely do we witness the occurrence of acne in any form before puberty, and how frequently do we obtain proof after the period that the influences of the sexual system is all-potent in so disturbing the tone that acne spots are produced. In girls menstruation is often attended regularly every month by fresh eruptions of acne, and in boys nocturnal emissions frequently have the same effect. If, however, the integument were originally thin and not greasy, then it is possible for the tone to be very seriously damaged by the causes adverted to, and yet no acne may be produced. In such cases pallor of skin may be the only result. In others in which there is less than usual proneness to inflammation, and perhaps very slight disturbance of tone, a peculiar form of lichen-acne, or very chronic persisting enlargement of the gland without congestion, may occur. This is seen chiefly in the temples and forehead, and in the male sex it is often coincident with similar long persisting enlargement of the glands on the penis and scrotum. The location of acne on the face is probably often explained by pre-existing peculiarities in the state of the skin of the face. Some get acne almost solely on the chin, or on the chin and cheeks, and these are almost always those in whom the nose is specially thin. On the other hand, those in whom the nose and skin are generally thick become liable when acne is developed to have the cellular tissue around the glands implicated as well as the glands themselves. Thus, tuberoso indurations of a very chronic nature may be produced, which, if in adult life the causes of aggravation remain, may advance from what is known as acne tuberosa to the grotesque deformities. Acne is very constantly hereditary, the same form

often prevailing in several members of a family, and acne tuberosa, I believe, often descends in several generations from father to son. I have not seen acne tuberosa more than once in women, and in that instance a sister of the patient had common acne, and here males had shown the tuberoso form. The pustular or common form belongs to youth, the rosaceous or erythematous to adult life. If, then, we attempt to reply to the question "What does acne in its various forms imply?" we should, I think, have to answer that, in the first place, it denotes original and heritable peculiarity in the structure of the skin; next, that its common form in young persons usually implies greater or less disturbance of tone in connection with the sexual system, and that its rosaceous form results from dyspepsia, attended by flushing of the face after meals. The tuberoso variety implies original peculiarity of structure, and is often aggravated by dyspepsia and intemperance. Common acne is almost constantly attended by proofs of enfeebled circulation, such as cold feet, and often by constipation. Closely associated with acne are the liability to styas, to some forms of sycosis, and to boils, but with these exceptions I know of no forms of skin disease which are due to the same class of causes, or denote the same conditions of health.

A few words may next be said as to the symptomatic meaning of eczema. This symptom is in a large majority of instances so far local that it is curable by local measures, and scarcely, if at all by constitutional ones, whether drugs or restrictions as to food. Yet it is probable that there is always a minor degree of constitutional proclivity and this is sometimes proved to be hereditary. In a few cases, dietetic restrictions do appear to have important influences as for instance, the forbidding of milk and sugar. I have already alluded to the remarkable way in which eczema appears to aggravate itself, and when once it has begun is its own source of extension. Probably a great many cases which become severe and general, might have been stopped in the beginning by appropriate local treatment. In most forms of eczema arsenic is useless, and this fact serves to detach it definitely from the psoriasis group. There are however certain forms of nummular eczema in which well-margined patches are scattered symmetrically over the limbs and trunk, in which the disease approaches very closely to a form of psoriasis, and is more or less under the control of the specific for the disease. Putting aside a very large number of mild or local cases, which are clearly due to local causes, we encounter severe eczema in the following forms: First, as a disease of the dentition period of infancy, or what is often equivalent, the lactation or milk-fed period. Second, as a most persisting and troublesome eruption affecting only special regions in children and adults, as for instance, the hands, the lips, and the anus. Thirdly, as a general and severe eruption in advanced adult or senile periods of life. It is a noteworthy fact that when infants who have suffered very severely get well, they usually get quite well, and remain well through life. General attacks affecting the whole body occur for the most part near the extremes of life. Applications containing tar, if weak enough, will almost always both prevent and cure eczema. Sea air is often definitely advantageous, and the disuse of milk and sugar are often important. With such facts before us can we find answers to the questions:—Is eczema usually a sign of gout, or any allied condition of defective digestion? Is it catarrhal? Is it due to structural idiosyncrasy of the integument? I should incline to reply that it is certainly not catarrhal in any correct use of the word. It is not produced by the common causes of catarrh, nor does it display the clinical course of all catarrhs in the tendency to spontaneous recovery and frequent repetition. Next in many cases it does imply a minor degree of mal-assimilation alleged to gout, and is benefited by abstinence from beer and wine. Recent experience has led me to believe that the offending article is often milk, and to think it of importance to restrict it as much as possible. In very many, a large majority of cases, there is no true gout either in the patients or relatives.

A GIRL named Blain died last week at Kildysart from the effects of hydrophobia. She was bitten about three months since by a dog, which was ultimately destroyed, after biting a number of cattle dogs.

THE USE AND ABUSE OF BLOOD LETTING. (a)

By W. F. WADE, F.R.C.P.,

Physician to the General Hospital, Birmingham.

AFTER a brief reference to the enduring value of the medical literature of 50 years ago, the lecturer proceeded to say that no one of the present generation, reading for the first time the clinical memorabilia of 1832, can fail to be struck by one all-pervading method of treatment—viz., blood-letting. Indeed, at first sight, it almost obscures our perception of any other therapeutical means or agents. The difficulty is to name diseases in which it was not used, not those in which it was. Its prevalence may be brought very vividly before us by a quotation from a contemporary author. He says: "Blood-letting is not only the most powerful and important, but the most generally used, of all our remedies. Scarcely a case of acute, or indeed of chronic disease, occurs in which it does not become necessary to consider the propriety of having recourse to the lancet, or to estimate the effects of blood-letting already instituted." But to get a full impression of this frequency, you must read, one after another, the records of cases in which—medical, surgical, traumatical, and obstetrical—bleeding from the arm was practised. Indeed, this does not exhaust the category. The chief resource of preventive medicine was to let blood from the arm every spring and fall.

Such was the practice of that day, and such, in large measure, the therapeutical science; for, be it observed, these things were done, not only by obscure apothecaries, but under the direction and auspices of those who constituted the highest court of scientific appeal.

Within a few years a revolution of opinion had taken place the like of which the history of medicine wots not of. For be it remembered, this was not the case of a transient phantasy—of a gourd which, having sprung up in a night, might well wither in a day—but the well-established practice of centuries, which had withstood, not only the ravages of time, but repeated volleys from the batteries of wit and satire.

To begin with the most remote predisposition: the medical profession cannot escape the influence of those phases of thought and waves of opinion which from time to time dominate other sections of the body politic. The intellect of that period was coming to distrust, and ultimately to banish, "violence, harshness—the darker shades of repression—from the education of the young, from the treatment of the insane, from the punishment of criminals, and to substitute for those time-honoured but most ineffectual processes a rational moderation." Well known political reforms were the work of that period, and the outcome of the spirit just mentioned. Reconsideration of ancient dogmas was the order of the day; and that reconsideration in many instances led to their effacement.

Another influence was coming into play. The *vis medicatrix nature* has been recognised in medicine from time immemorial; but its efficiency as an antagonist to disease has been at different times very differently estimated. The formula may be the same, but the conceptions it embodies may differ to an extent which is equivalent to a difference in kind. It would seem that formerly Nature was esteemed but a very feeble and humble assistant, whose influence was nothing unless rigidly controlled and directed by a more intelligent or reinforced by a more potent agent. This idea was all in favour of robust and strenuous therapeutics, and they were accordingly dominant. It was assumed then that Nature could do nothing without assistance. We do not assume, but know as a matter of fact, that in many instances Nature unassisted can do everything. "Expectant medicine" is the term used to designate the line of conduct, or perhaps rather the mental attitude which this knowledge imposes upon us. This is sometimes derisively described as the art of laboriously doing nothing—of trusting to Providence, and it is supposed to be a lazy, shiftless mode of shirking responsibility. All sound principles are liable to corruption; and this particular principle may—indeed, in the hands of those who do not appreciate its essence, does—lead to a neglect of therapeutical means. But, rightly understood, it is anything but a lazy and shiftless method; it necessitates a constant, anxious, and laborious study and observance of the tricks and turnings and vagaries

of disorder and disease. So far from this system, when intelligently followed, leading to a disbelief in the potentiality of drugs, it seems to me to do exactly the opposite. Having learnt with more accuracy and greater fulness the natural progress of disease, we are the better able to estimate the extent to which the direction of that progress is capable of deflection by the administration of remedies; and it passes my comprehension how any person who has intelligently and dispassionately watched the progress of disease, when subjected and when not subjected to drugs, can refuse to believe that we hold in our hands gigantic forces to oppose to those of an aberrant Nature. Extremes meet; and it may be that in this and many other cases incredulity is a token of a credulous nature. Various causes, no doubt, co-operated in generating and maturing expectant medicine. One which we know did at a later period markedly contribute to its development was even at this period beginning to attract attention. Laymen for the most part do not pretend, and do not seek, to understand the merits of opposing medical theories or schools of thought. It is on this broad ground, and as an historical fact, and not a critical opinion, that I say that Hahnemann was commencing to subject, not so much the public mind to his doctrines, as the bodies of the public in this country to his treatment. He had by this time evolved out of his inner consciousness the belief that infinitesimal particles might have what seem to us preternatural powers instilled into them by the divine agency of the pestle and mortar. If it was not the "little-dose" element which made this system attractive to the laity, certain it is that this chiefly fixed the attention of the profession. To say that the trituration doctrine is so absurd that no sane person can possibly believe it, is to ignore a great part of the history of speculative thought in all ages and countries; but it is just to say that the adoption of such a dogma requires an unusual share of that mystical element of which the mind of no one is entirely devoid. This view explains why, to the great bulk of the profession, the doctrine of infinitesimal doses dynamised by trituration was, and remains incredible. Rightly or wrongly, cures apparently wrought by such medicaments were and are judged to be instances of spontaneous recovery. This interpretation necessarily facilitated the reception of that higher ideal of the power of Nature which was then arising; indeed, from that it is possible that the suggestion proceeded. Such a conception would undoubtedly make more easy the relinquishment of severe and violent modes of treatment, and amongst these blood-letting was conspicuous.

The second source of error is a too rigid adherence to the dictates of science. This cannot be treated so peremptorily. That medical science as a whole is imperfect; that the individual sciences of which it is composed are imperfect; that of these the science of therapeutics is the most imperfect; that above all, we, the agents who have to apply these sciences in our daily life, are imperfect—all this is not only true, but is universally admitted to be so. The doctrine that we must incessantly compare that which does happen with that which we think ought to happen is therefore no new one. Yet those who venture to submit rules and methods which, it is hoped, may minimise these defects, are somehow disposed to disparage, if not to dethrone, science, and to be wishful to replace it by some fanciful hocus-pocus of their own. Nothing can be more unjust, nothing can be more injurious, not to those who use, but to those who reject precautions and safe-guards, and to the science which they honestly desire to exalt. Disguise or dislike it as we may, it is not the less certain that, in the treatment of disease, we have no firmer basis than the doctrine of probabilities. And he who manfully recognises this is the least likely to fall into error, and the earliest to find out when he has done so, and, therefore, the promptest to retace his steps. In medicine, we have, in an ordinary way, to deal with some things which are highly probable, some fairly probable, some slightly probable, and some improbable, some only just possible, but with nothing absolutely certain and nothing absolutely impossible. This is not a reasonable cause for discouragement, still less despair, though it is a reasonable cause for reflection, care, and thoughtfulness.

There are special occasions in which we are all prone to misuse drugs, sometimes straining, sometimes neglecting the teachings of science. We have all seen the acute case going wrong, sliding, we know not exactly at what first moment, or how, out of our grasp. We see looming in the not remote distance the cliffs which overhang the valley of the shadow of death.

(a) Abstract of the Address in Medicine delivered at Worcester, August 9th, before the British Medical Association.

Is it not true that, thus tried, our composure may become disturbed, our judgment clouded, that our conduct, instead of being controlled by calm consideration, may be misguided by panic? Does it never happen that, not knowing what to do, we resolve to do something? Does this something never take the shape of a potent drug in what is miscalled a heroic dose, administered without a sufficient possibility of being able to predict its effects? No one dissents from the propositions, that meddling surgery is bad surgery, that meddling midwifery is bad wifery. Do we at all times adequately realise that there may be a meddling medicine which is bad medicine? Standing in the dark on the brink of a precipice, may it not show more wisdom, and require more courage, so to stand, than to take a free step, not knowing whether it may land us in security or precipitate us into the abyss?

We have now seen that there is more than one way of misusing remedies. In all these ways, our predecessors from time to time, as we may see from the records, misused blood-letting. In this misuse we find the real origin of its abandonment. In 1820 a provincial practitioner, a physician at Nottingham, Marshall Hall, opened the first parallel of the sage which, in my opinion, eventuated in the razing of this stronghold.

In 1829 he brought to bear on the abuses of blood-letting in a more elaborate criticism, new facts, and a more matured opinion. Instances are given where the sagacity of experienced practitioners had intervened to shield patients from the fatal effects of a too servile submission to the accepted teachings of science. Other instances follow in which honest reliance upon these teachings resulted in the patients being bled to death. The cases are on record, and will convince the most unwilling reader, that this is not a sensational or rhetorical statement, but the simple, unvarnished, if unpalatable truth. If all this be so, who can challenge our duty to exercise the right of private judgment? But this exercise, if it is to be salutary rather than misleading, must not be reserved for cases of exceptional complexity and difficulty; it must be habitual, daily, hourly. Trivial cases and familiar drugs should be to us what academy studies and jottings of nature are to the painter, reviews and field days to the soldier, scales to the vocalist—the means by which we perfect ourselves in the details which have to be happily combined to make the supreme effort successful.

We come now to an episode in the investigation which, beyond its historical interest, has an important bearing on a question which is just now subjected, not to philosophical criticism, but to a vehement, heedless, rhetorical guerilla. After ten years devoted to investigating the effects of loss of blood, having amassed cases and accumulated observations, not ignorant of the strictures of previous writers on the abuse of blood-letting, in possession of a real clue and well advanced on the right track, deeply penetrated with the importance of the inquiry, and profoundly anxious lest while purposing to benefit humanity by promulgating truth, he might inadvertently injure it by propagating error, in 1830 Marshall Hall undertook some experiments on living animals. But hear from himself his reasons. He says:—

“After paying considerable attention to the effects of loss of blood, as manifested by the human subject under the influence of blood-letting or hæmorrhage, I still felt that there were so many questions left in obscurity, that the investigation of them in the way of experiment was one the object of which was at once legitimate and most important.

(1) “It was highly important to ascertain the effects of loss of blood in circumstances entirely free from the complication of disease or other unusual condition of the system.

(2) “It was highly important to estimate the difference in the effects of loss of blood in the different ages.

(3) “It was also highly important to fill up a blank left in my former investigations by ascertaining more accurately and distinctly than before the various organic changes induced by loss of blood.

(4) “And as blood-letting constitutes the most powerful of our remedies, and hæmorrhage one of the most formidable of diseases, it became of the utmost moment to fix the rules and limits of the employment of the former, and to ascertain the most efficacious mode of restoration in the latter.”

These words may have been, and, according to some, I presume, were the specious covering which a cruel and blood-thirsty man, reckless of animal suffering and regardless of all moral duty, used to cloak his inherent savagery. May they

not have been the truthful words of a just and righteous philosopher offering reasons for resorting to proceedings primarily repulsive to his feelings—proceedings which were nevertheless, in his pondered judgment, obligatory for the complete elucidation of an obscure subject of direct and paramount importance to the cure of his fellow-man? Sitting here, the inheritors of this knowledge, which has indirectly changed the whole face of our practice, it may seem to us that the case was overloaded with proof. But it is impossible to decide, after the event, what amount of evidence ought to have been sufficient to fashion and consolidate into a coherent and shapely form the flocculent masses of colloidal truth floating hither and thither in the mind of a discoverer. War against the cherished convictions of the age is not to be undertaken with a light heart, nor with an incomplete armament. At any rate, the other evidence did not seem to Marshall Hall sufficient to overcome the *vis inertiae* of contemporary opinion. For in 1836 he deemed it necessary to publish, in a more extended and complete form, and reinforced by his vivisection experiences, the views which he had already on several occasions propounded.

To return now to our proper subject. In the year 1836, Marshall Hall's last word on bloodletting was published. But a very few years elapsed before it had ceased to be practised. It is most curious that the intention and object of his publication was to regulate, not to abolish, bleeding. It is true that he clearly demonstrated that it might be, and had been, so employed as to produce not only injurious, but distinctly fatal, effects; but he also taught its utility, authorised, and, indeed, recommended its employment, though with limitations not previously laid down. How, then, it may be fairly asked, could such teaching result in its abandonment? The printed records show distinctly that this remedy had come to be used in all sorts of cases, at all sorts of times, as a matter of course; as one that could do no harm at the beginning of an illness to cut it short, in the middle as routine treatment, and when things became desperate as a forlorn hope—as the last, the only chance. The plain blunt statement that persons had been bled to death *secundum artem*, the simple detail of the facts of individual cases, proving to the most unwilling reader that this statement was true, must have pricked the conscience of many an honest practitioner. Men came to look at bleeding from an exactly opposite point of view to that which they had previously occupied, and began to see that it was not absolutely necessary at the onset of disease, was of doubtful safety as a routine treatment during its height, and at a grand crisis might even be fatal. Can we wonder that in a few short years the practice had ceased to exist?

It would be improper, and indeed might be misleading, to leave this subject without adverting to another explanation of this astonishing change in practice. It has been attributed to a change of type in disease. A chief supporter of this view is one of the ablest and worthiest representatives of medicine in our time—worthy, indeed, of any age—Sir Thomas Watson. What has not been shown, he says, writing in 1857, “is that the human constitution is incapable, from influences to us unknown, of undergoing alterations, in respect to the manner in which it is affected by inflammation, and by the reputed remedies of inflammation. For my own part, I am firmly persuaded, by my own observation, and by the records of medicine, that there are waves of time through which the sthenic and asthenic characters of disease prevail in succession; and that we are at present living amid one of its adynamic phases.”

It is not necessary to discuss the soundness of the view so succinctly stated. For the purpose of my argument, I could have wished to be able to give it an unequivocal assent. It enforces, with the most eloquent brevity, the supreme and paramount necessity of a constant, even suspicious watchfulness, of our own operations and of the workings of nature. Let us now turn to some further considerations which especially enforce this obligation.

Whilst unreservedly admitting that medicine is imperfect, we all believe that it is not stationary, but progressive. Each year furnishes more exact knowledge as to the structure of the body; the uses of various organs; their *modus operandi* in health; the manner in which their operations are disturbed by disease; the effect of such disturbance upon other organs; the causes of these disturbances; and the extent to which they may be controlled or interrupted by diet, drugs, or other agents.

We are from time to time presented with new instruments, or new means of exact research, with new drugs, and with new

facts or theories respecting old ones. But this is by no means all. We are furthermore being, not infrequently, urged to apply this new knowledge, or these new views, to the treatment of disease; to employ a new drug, to discard an old one, or to use it in conditions to which it has heretofore been considered inapplicable, or to use it in doses of much less or of much greater magnitude than we have been wont to administer. Examples will at once occur to your minds of beneficial changes which have of late years been in this way introduced. It is possible that we may have to go much further in some of these directions. As regards the dosage of drugs, I am strongly inclined to think that, both as regards *maxima* and *minima*, we are too closely bound by the fetters of posological tables, or of our habitual prescriptions.

But let us look at the other side of the shield. It is not many years since a provincial surgeon of ability and of local repute began to employ and recommend a new plan of treating delirium tremens. He gave tincture of digitalis in doses which, compared with ordinary ones, were simply enormous. In support of his views, he cited cases in which these huge doses appeared to have produced the most beneficial results. One thing appeared certain, that, contrary to anyone's anticipation, these doses had not proved fatal. The facts were puzzling to most. There is always a class of minds who have no difficulty in dealing with such a case; if the inferences appear unavoidable, but inconvenient, they disbelieve the facts. Nothing can be more simple. Some supposed that the drug employed was of inferior quality, and therefore comparatively inert. To others who looked a little deeper, it seemed probable that there were conditions of the body which might bear and even profit by doses which, under other circumstances, would be poisonous; that these conditions were present in some, but not necessarily in all cases of delirium tremens; that before long, cases of this disease might present themselves in which these particular conditions were not present, and that, if so, we should hear of fatal results from this plan of treatment. This is exactly what happened; and on this the practice, so far as published data show, passed away. It is too probable that the reaction went to the extent of unduly limiting the use of the drug in those cases of delirium tremens where, in moderate quantities, it is most advantageous. It is not in the case of blood-letting only that we see that a remedy, while it has a good name, is used in season and out of season, but, if its name become tarnished, not at all.

The error of Todd mainly arose from that fertile source of medical—we might truly say of human—error, hasty generalisation. He had no doubt seen, as who amongst us has not seen, the revivifying effects of a dose of brandy opportunely administered. He had, no doubt, as we all have, seen the patient rescued by a few repetitions of this dose from the door of death to which he had been brought by an internal inflammation. The change is nothing less than the transformation of a scene where hope seemed ridiculous into one where anxiety seems absurd. The thought naturally arises, why not prevent the advent of such an alarming condition by beginning a little sooner to administer so sure an antidote? To the soundness of this suggestion no just exception can be taken, for undoubtedly the experienced eye can discern the storm coming, without waiting till its bursting has announced its existence and destructiveness. So far then, so good. But having got so far safely, it is easy to go still further, and to get on to dangerous ground. Why not begin at the beginning? Why not give the alcohol as soon as you know, and this is not difficult, that you have to do with an inflammation? The acceptance of this reasoning involves perilous consequences. Few minds are so delicately balanced as to be able to distinguish between such a position and the adoption of alcohol as an anti-inflammatory specific. You will not ask me for a metaphysical analysis or definition of the term "specific." But you will permit a few remarks upon the practical dangers arising from the conception which it embodies.

The medical mind never has ceased, and probably never will, to hanker after specifics. From time to time some drug is elevated by its undeniably remedial effects into this position, and our hopes are flattered that we possess one. The idea is most grateful. In the first place, what a saving of labour, thought, and trouble; nor is there anything in that feeling of which we need be ashamed; for with many specifics to lean on, our lives would be sufficiently arduous. Then again, we all feel, though perhaps we may try to hide it from ourselves, the uncertainty of medicine. How delightful to know that, to the credit of our own reputation, and to the ad-

vantage of our patient, we have, for at least one disease, a remedy that cannot fail.

It is true, probably, that no one of us believes in the existence of an absolute specific which can never fail; but, on the other hand, we must remember that the conception of a specific and the conception of failure are reciprocally exclusive. A vivid mental picture of the one necessarily implies a very shadowy perception of the other. One reason why this yearning for specifics is so likely to mislead us is that it almost inevitably involves a conception of disease as a unity, instead of a complexity, of processes.

We cannot wonder that the idea of driving the patient through difficulties, as an engine may be driven through a snow-drift, has assumed in some minds an undue magnitude. But the influence of this notion was not limited to the case of acute disease. The progress of medical science has for some time been most marked in the elucidation of the nature and results of organic disease. The hopelessly irremediable character of the changes here found has certainly tended to enforce the idea of "nourishing, supporting, and building up." From this point, the same idea has spread to an earlier stage in such cases, the stage of incipient disease, or to even an earlier stage, that of threatening or impending organic changes—a pre-organic stage. May it not happen, has it not happened, does it not happen, that sometimes this truly important consideration is suffered to overshadow other considerations also truly important? Is there not danger that what we will, merely for convenience and brevity, call the physiological basis of treatment, may be insufficiently resorted to; that the diseased organ itself may not be adequately helped, and coaxed, and assisted to do yet a little more work; that its oppressed and labouring neighbours may in like manner be left without due succour? If it be important that we should get a complete mental grasp of the whole of the case, it is mainly so that we may be the better able to disintegrate it into its constituent elements; that, having so resolved it, we may the better see what we can and what we cannot cope with. How it might have altered the past, had the custom been universal for each one to ask himself, before deciding on a plan of treatment, these questions: What do I propose to aim at? Why do I do so? How best may I effect my object? Might not such a method also alter the future?

We must, to a large extent, depend each one upon himself, his own observation and his own private judgment; employing the best means and devices of science to ensure accuracy of observation, and exercising our judgment with caution and modesty. To the few only is it given to extend the landmarks of science, or to reclaim the waste lands of ignorance. But to each one is given the power to cultivate and utilise those which have been reclaimed. To each one it is given to make the practice of medicine more rational, more common sense, and therefore more truly scientific; to render more rare in the future such dark blots as we have regretfully recognised in the past.

ANÆSTHESIA, ANTISEPSIS, AND OSTEO-GENESIS. (a)

By WILLIAM STOKES, F.R.C.S.I.

Professor of Surgery, Royal College of Surgeons, Ireland; President of the Pathological Society of Ireland.

HAVING referred to the approaching changes in the system of medical education and licensing in the United Kingdom, the lecturer proceeded:—

It has hitherto been customary for my predecessors at the annual meetings of the Association, either to give a *résumé* of the most recent advances in surgery, and discuss some particular theory or mode of practice on which surgical opinion is more or less unsettled, or dwell on those topics that have proved of special interest to himself. On the present occasion, one which should be marked *melioris lapillo*, to give a detailed retrospect of surgical advancement during the past half century would be a task not alone difficult, but, in truth, impossible in the time at my disposal. I purpose, therefore, to dwell on some few topics of great general interest, involving questions still unsettled, and which have more particularly engaged my attention.

(a) Abstract of the Address in Surgery delivered before the British Medical Association at Worcester, August 10th, 1882.

What have been our advances? The list is a goodly one, and the mere enumeration of them would alone occupy the hour at my disposal; but I may mention a few of those that stand out most boldly in relief: The abandonment of an indiscriminate blood-letting in almost every form of acute surgical disease, of a reckless use of mercury in the treatment of syphilis, and of setons and moxæ in hopelessly irremediable articular and other diseases; the introduction of the pressure treatment of aneurism by Bellingham, Todd, and Hutton; of drainage in the treatment of wounds and abscesses by Chassaignac; of metallic sutures and the perfecting of the operations of vesico-vaginal fistula by Marion Sims; of lithotrity by Civiale, Thompson, and Bigelow; and of stricture by Syme, Wheelhouse, Maisonneuve, Perrève, and Holt; the *renaissance* of joint-resection by Crampton, Syme, and Ferguson; the introduction and establishment on a firm basis of ovariectomy by McDowell, Clay, Spencer Wells, and Keith; of bloodless surgery by Eschschsch; of skin-grafting and sponge-grafting by Reverdin and Hamilton; and of osteotomy in genu-valgum by Ogston; improvements in methods of amputation by Bell, Teale, Carden, Syme, and many others; also the operations of gastrostomy, excision of the pylorus, of the spleen, the kidney, supra-pubic excision of the uterus, laparotomy, and cholecystotomy. In connection with abdominal surgery, I would also allude to the recently-published able essays by Sir William MacCormac and Dr. Marion Sims, the latter paper dealing mainly with antiseptics and drainage in gun-shot wounds—these being, in Sir James Paget's opinion, "the most important perhaps of all the provisions to be made in healing wounds." Again, we have torsion in the treatment of hæmorrhage—a method to which such an impulse has been given by Mr. Bryant; and the treatment of aneurism by arterial ligation, without injury to the deeper structures of the vessels, by the methods of Porter and Barwell. In two cases I adopted Porter's method, using a wire, deligating the femoral artery in one, and in the other the abdominal aorta, Barwell's ligature—made from theorta of an ox—a method recently tested in the Richmond Hospital by my colleague, Dr. Thomson, who deligated the arteria innominate for subclavian aneurism. Again, we have, in the treatment of fractures, immovable splints, and improved methods of extension by weights, or more perfectly by screw action; of manipulation in the treatment of luxation; and, in spinal disease, the use of the plaster-jacket of Sayre.

I need not dwell on the complete revolution in ophthalmic and aural surgery that has occurred, and of the light that the ophthalmoscope of Helmholtz has shed, not alone on ophthalmology, but on pathology in its widest sense; or on the other instruments of precision constantly made use of. Memorable as these advances would make any era in the history of surgery, they all pale before three I have yet to mention—advances which the surgical historian will doubtless point to and emphasise as the three giant strides that the past half century has witnessed. I allude, first, to the discovery of the means of banishing pain during the performance of surgical operations; secondly, to the restoration of diseased or injured bones and joints necessitating resection; and, thirdly, the enunciation of the principle and establishment of the practice by Pasteur and Lister of antisepticism in the treatment of wounds.

To anesthetics, antiseptics, and osteogenesis, together with a few cognate topics, I would therefore now invite attention.

Whatever anesthetic the surgeon selects—whether it be chloroform, ether, or both combined, bichloride of methylene, or nitrous oxide gas—we must admit that, even with the most careful precautions as regards the condition of the patient generally, the anesthetic selected, the amount of it used, and the mode of its administration, the gauntlet of peril has still to be run. In truth, it is hardly to be expected that an agent which can so rapidly and completely paralyse our senses should not be attended with peril. Of the two anesthetics, however, that surgeons as a rule mainly rely on—ether and chloroform—much has of late been done to diminish risk by limitation of the amount of the anesthetic used; by the gradual introduction of it into the system; by the avoidance of either in infancy and extreme age, in the puerperal state, in hysteria, and also when there is reason to suspect the existence of any acute or chronic form of renal or pulmonary disease. In the use of chloroform the ever-present risk of cardiac paralysis appears to be increased when any functional or organic

disease of the heart is present, and is, therefore, in such cases, distinctly contraindicated.

Although the number of accidents connected with the use of anæsthetics is fortunately very limited, still I feel sure that by more accurate knowledge of the facts I have mentioned, by entrusting the duty of administering anæsthetics solely to persons of experience and judgment, and by a stricter adoption of the rule so happily formulated by Mr. Jonathan Hutchinson in reference to the desirability of using chloroform in cases below six and above sixty years of age, the number of these regrettable accidents would be still further largely diminished. In the majority of cases, however, I would unhesitatingly prefer ether. In using it there is greater economy of time; it is, with the necessary precautions taken, safer; there is, as a rule, less sickness, and the return to sensibility is slower. To obtain these advantages—which, with others, have been so well and systematically formulated by Mr. Teale—regard must be largely had to the method employed of administering it; and I am of opinion that one in which the air is rebreathed by the patient, as in the inhalers of Morgan, Ormsby, and Clover, should be preferred, as so great an economy is effected thereby, not alone of ether, but what is of far greater importance, of heat in the air-passages, the inspiration of a large quantity of cold ether vapour tending to induce respiratory syncope.

Considering that the treatment of wounds is, in Professor Humphry's words, not merely "the first stone, but also the corner-stone of surgery," antiseptic practice should rank, in my opinion, as the greatest of the surgical advances that the past half century has witnessed. It deserves a special attention not merely on account of the results of its adoption, but also because surgical opinion is still so divided about it—an unsettlement to which an impulse has been given by Mr. Savory's remarkable address at Cork, and by the observations on the value of carbolic spray made by Mr. Lister himself at the International Medical Congress last year. As regards Mr. Savory's denunciation of Listerism, I would say that, after reading it, and also the able reply to it by my colleague, Dr. Thomson, one cannot but come to the conclusion that, when the address is stripped of all its brilliant eloquence and rhetorical decoration, two facts are, to our surprise, brought clearly to light. One is the admission of the germ theory of putrefaction; and the other, that the method of dressing employed by Mr. Savory is essentially antiseptic, consisting as it does of many of the features that characterise Listerian dressings—for example, carbolicised catgut ligatures, carbolicised oils, drainage, and washing the wound with a weak permanganate of potash lotion, or "some other potent antiseptic." Now, as the author of the reply to which I have referred properly asks, "Is this method fittingly characterised by its simplicity and the entire absence of all novelty?"

In reference to Mr. Lister's statement on the value of carbolic spray, about which there has been so much unfortunate misconstruction and misunderstanding, I would certainly say he did not surrender his position in any way. He did not, as was said to me, in terms more picturesque than accurate, by an eminent surgical friend on that occasion, "inter antiseptic surgery and then sing a dirge over." On the contrary, he stated that he looked forward to obtaining a more perfect and convenient mode of asepticism than that afforded by carbolic spray.

Considering the subject from a purely practical point of view, it appears of little consequence whether we accept the views recently discussed by Dr. Burdon Sanderson, or those of Ogston and Hueter, the former maintaining that the inflammatory exudates of a wound do not depend primarily on the contact with them of atmospheric organisms, but that their secondarily infective character does; in other words, that atmospheric organisms *per se* are not necessarily a source of danger, nor do they predispose to the formation of inflammatory exudates, but they do exercise a baneful influence on the latter by rendering them infective. To quote his words, "they are not so much mischief-makers as mischief spreaders." Two distinct functions are attributed by Burdon Sanderson to these organisms; one "of developing what may be called the phlogogenic infection, and that of conveying it to all parts of the body." Ogston and Hueter, on the other hand, maintain and furnish strong arguments for their views, that septic organisms are primarily the sources of all the inflammatory and other troubles

to which wounds are liable, and that under aseptic conditions these dangers can be avoided.

The essentially weak point in the persistent and obstinate opposition to Listerism is the almost universal admission of the truth of the germ-theory of putrefaction. If the fantastic theory of heterogenesis had not long since been swept into the deserved limbo of other exploded doctrines, there would be some scientific standpoint for those opposed to Lister's theory and practice. But not having this, and admitting the truth of the germ theory of putrefaction, they surrender their position. An attempt has been made by Mr. Lawson Tait to draw a distinction between the effects of germs on dead and living tissues, the only serious consequences being, it is alleged, those which result from their introduction into the system through the medium of dead tissue. Such is the contention. In a word, it comes simply to this—that if the dead tissue factor were non-existent, the organisms would remain harmless; if, on the other hand, it be present, they become hurtful. But those who hold this view ignore the elementary fact that there never was a wound, and especially one in which vessels are tied or twisted, in which dead and living tissues were not at once brought into contact. Assuming, however, that this was not the case, has it not been shown on clear evidence by Dr. Burdon Sanderson that septic agencies generated in the organism may induce idiopathic inflammation without the medium of dead tissue? Also that, in acute peritonitis, septic organisms can, through the medium of the lymphatic vessels, be conveyed into the blood streams, and, to use his words, "carry with them a phlogogenic virus, by virtue of which, wherever they lodge, they become the starting-points of infective abscesses." Again, that similar phenomena are observed in connection with ulcerative endocarditis, confirming the observations of Weigert that, in variola, they find their way "in myriads" into the circulation, and eventually find a resting place in the capillaries of the internal organs, where they become nuclei of infective abscesses.

Those who advocate and practise what they are pleased to term a "modified" antiseptic system, attempt, in fact, in a roundabout, clumsy, inefficient way, to do precisely what those who practise Listerism achieve by means which are the outcome of accurate scientific research.

It has been stated that ovariectomy should be considered the touchstone of the efficacy of the antiseptic treatment of wounds. I do not think so (although my successes in ovariectomy date from the time I adopted the system), and for the reasons given by Professor Lister. First, the disposition of a large serous membrane to absorb rapidly the plasma from the cut surface, the absence of tension, the high vital power of the peritoneum in uniting after being wounded; and, lastly, that bloody serum is an unfavourable medium for the growth of micro-organisms, a fact directly at variance with the dictum of Keith, that it is the "enemy of the ovariectomist." One of the best tests, if not the best, for the value of antiseptic practice is resection of the knee-joint, as there are so many circumstances that militate against immediate union being obtained after it. In the first place, the cases requiring so formidable an operation are, as a rule, in a condition of great physical exhaustion consequent on long confinement, and probably protracted suffering of mind and body. The wound is of necessity a large one; the operation occupies a considerable time; two large freshly cut bone surfaces are made, between which union is to take place; and, lastly, there is the great difficulty of keeping it, no matter what appliance be adopted, the limb absolutely at rest during the process of union. Before the adoption of Listerism the surgeon anticipated that four, six, or eight months, or longer, would elapse before union took place, and it was always a subject discussed at consultations on these cases, previously to operation, whether the patient would have strength to endure so protracted a suppuration. As an illustration of how changed matters are now, in a series of fourteen of my cases of excision of the knee-joint, the wounds in nine of them united without a trace of pus production; and in the last of them only two dressings were required subsequent to the one applied at the time of the operation, and in seven weeks after the patient was up and going about. Another antiseptic triumph was the case of a boy with extensive necrosis of the fibula, sinuses, and suppuration existing at the time of the operation. I excised subperiosteally the diaphysis of the fibula, and the case pursued a perfectly aseptic course,

the evidence of new bone-formation being also incontrovertible. From the fact of there being no pus production subsequent to the operation, notwithstanding the pre-existence of suppurating sinuses, a special interest attaches itself to this case. I can only account for this exceptional circumstance as a result of the careful washing of the sinuses by carbolic acid and zinc chloride solutions.

As regards the hygienic effects of the practice, I may mention some facts of interest noticed by me and my colleagues in the hospital to which I am attached. The building is a very old one, and was not constructed originally for a hospital. None of the more modern arrangements, now considered so essential, as regards heating, light, ventilation, &c., exist. It is situated in a poor, very densely populated part of the city, with tenement houses, dairy yards, cattle sheds, and stables in its neighbourhood; and some of the houses in its immediate vicinity have been designated by the medical officers of health as "fever nests." When I was a student there erysipelas and pyæmia were not unfrequently observed after operations even of no great magnitude; hospital gangrene, too, I have seen several instances of—in fact, these three diseases constituted a grim trio, of which the surgeons had not unnaturally a dread. Let it not be thought that the occurrence of these was in any way to be attributed to want of care and attention to cleanliness. No cases could in this respect be more conscientiously or carefully managed. What now exists? Hospital gangrene is an extinct disease, nor have we observed, during a period extending over six years, a single case of erysipelas, septicæmia, or pyæmia following an operation in which the practice of Lister was accurately carried out; *accurately*, for everything depends on that. The practice has been well compared to a coat of mail, which secures the wearer so long as it is perfect, but any missing link in which may admit the *lethalis arundo*.

Similar testimony to what I and my colleagues can state has been given by many foreign surgeons of eminence, among whom I may mention Von Nussbaum, Bardeleben, Thiersch, Von Langenbeck, Volkmann, Esmarch, Saxtorpf, Championnière, and many others.

Although I do not regard surgical statistics with the reverential awe that some do, who look upon them, in fact, as a sort of tribunal beyond which there can be no appeal, I observe that in a record of upwards of six hundred operations performed by myself and my colleagues at the Richmond Surgical Hospital, during the past three years—an institution which I have already spoken of as being hygienically in so unsatisfactory a condition—the mortality was 3·6 per cent.; and there was not a single case in which Listerism was accurately employed that was followed by any infective disease.

The discovery of anæsthetics, and the means of inducing osteogenesis, have largely widened the field of practical surgery. When we consider the revolution that has taken place, since the introduction of antiseptics, in the treatment of compound fracture, of abscesses—especially those symptomatic of bone-disease—of bursal tumours, of congenital as well as acquired osseous deformity, of ununited fractures, including those of the patella and olecranon, of foreign bodies in joints, of hæmorrhage and aneurism by antiseptic ligature, and of various diseases and injuries of the abdominal organs indicating the operations already mentioned, this may, I think, be said with even greater truth. To these may also be added certain thoracic affections, such as empyema, pericardial effusion, and pulmonary abscess, by which the wide gulf that so long existed between medicine and surgery has been to a great extent bridged over—uniting them together firmly, strongly, and for ever.

The methods adopted for bringing about a regeneration of bones and joints necessitating resection on account of injury or disease, constitute an advance in surgery of such interest and practical importance as to distinctly merit special consideration. To adopt a measure by which the main support of a limb, when diseased, and not only rendering that limb useless, but also perhaps imperilling life by pain and exhaustive suppuration, can be removed, with not a mere probability, but, in many instances, almost a certain confidence that it will be restored to the patient, is a triumph then which it is hard to conceive one of greater importance among the developments of modern surgery. The subject has been of keen interest to me for many years, since the time when, in 1865, I witnessed in Lyons many of M. Ollier's experiments, and subsequently repeated them. Strongly impressed by what I then

learned, I have since in practice, as suitable cases presented themselves, adopted periosteal preservation in various operations on bones and joints, a procedure with which the names of the eminent surgical trio, Syme, Langenbeck, and Ollier, must for ever be associated. The operative measures on which my experience is based are resections of the elbow, shoulder, and ankle-joints; resection of the diaphysis of the fibula in its entirety; resection of the greater portion of the ulna; of metatarsal and metacarpal bones; and, lastly, of transplantation of periosteum, as a part of the so-called Indian rhinoplastic operation. Still, though the good results obtained by this practice are, in properly selected cases, not open to question, there can be no doubt as to the existing unsettled condition of surgical opinion in reference to the value of the procedure. This, I believe, arises from a twofold cause, one being traumatic, from insufficient care being taken during the detachment of the membrane, and the second, the non-differentiation on the part of surgeons of the cases likely to be benefited, and those in which the adoption of the practice is, as a rule, attended with disappointing results. As to its value, when the membrane is comparatively healthy, and the patient young, there can be no question. The activity of bone production and other signally gratifying results of the practice must be acknowledged when performed under these circumstances. These results, however, are not so striking when the patient is an adult. In some cases, no bone production whatever is observed, and in others the osteogenic process is slow, the product weak and liable to become absorbed. It should also be borne in mind that, in early life, the membrane has a dual function; one, that of increasing the thickness of bone, and the other the repair of waste. In adult life, it is mainly confined to the latter. This rule, however, is not without exception. One instance I can recall of a man, aged 42, on whom I performed a resection of the upper end of the humerus on account of carious disease. The result was eminently satisfactory; not only was there a reformation of the bone removed, as evidenced by comparative measurement, but also a pseudo-arthritis so perfect as to enable him now, as I have recently learned, to use his spade, to plough, and perform with efficiency all the ordinary duties of an agricultural labourer.

Another point worthy of consideration is the value of the practice in adults and children when the membrane is found to be thickened and pulpy. Among the former, as mentioned by M'Ewen, the osteogenic layer is, as a rule, found to be destroyed, the outer layer thickened, vascular, and lined with granulation-tissue, which soon undergoes fatty degeneration. From such a condition no bone production could possibly be anticipated. On the other hand, a thickened, vascular, cell-infiltrated, softened condition is not incompatible with its osteogenic layer being intact, and its activity in bone production unimpaired; in truth, not unimpaired, but exalted, as we observe in acute necrosis, and also in the development of syphilitic nodes. The condition of fatty degeneration of the osteogenic layer is found among both adults and children, but more frequently among the former. When found among the latter, the cases are, as a rule, badly nourished, anæmic, weakly, and scrofulous. The thickened, vascular, but intact condition of the membrane is what is observed among young persons, and its preservation, therefore, is obviously indicated. In adults it is rarely observed.

The efforts to produce bone in experiments on the lower animals by periosteal transplantation have not been attended with any very marked success, nor have similar attempts in man been specially encouraging. In only one instance did Ollier obtain distinct evidence of bone formation from grafted periosteum. In the Indian rhinoplastic operation, I have undoubtedly succeeded, after transplanting the membrane from the frontal bone, in satisfying myself of the existence of bone reproduction. When left attached to bone, as in Von Langenbeck's modification of this operation, the result has not been so good, owing to the liability to necrosis of the transplanted or detached portions of bone.

As regards bone transplantation I cannot speak from any personal experience; but, in connection with this all-important subject, I must allude to the great stride made in this direction by Dr. M'Ewen of Glasgow. The case of inter-human osseous transplantation in which over two-thirds of the shaft of a humerus was restored, and an account of which was communicated to the Royal Society last year, is one which must stand out in bold relief in the history of this new departure in operative surgery—one

which is with many others an outcome indirectly perhaps, but not the less a result, of antiseptic surgery. For the experience derived from observing the progress towards good union and without pus production of bad compound comminuted fractures when pieces of bone completely separated, and even detached from periosteum, have, after being antisepticised, been replaced, lived, and eventually united to the neighbouring osseous structures, tends, as M'Ewen has pointed out, to show the probability of transplanted bone living. The practice of inter-human osseous transplantation is one which of necessity is applicable to only a very limited number of cases, and the means of carrying it out must rarely be available, as fresh, human, healthy osseous transplants cannot often be obtained. The case, however, which I am glad to say I had an opportunity of examining, is so pregnant of interest, and so suggestive, that it must serve as an incentive to further effort to guide and encourage those working in this direction.

Clinical Records.

GLASGOW OPHTHALMIC INSTITUTION.

Detachment of Retina—Cured by Operation.

By A. T. THOMSON, M.D.

THIS case is interesting because, although it is now about four years since Dr. Wolfe suggested the operation to the profession, and Dr. Shand recently recorded another successful case from this clinique, where the operation is adopted as a successful procedure; yet ophthalmologists still regard detachment of the retina as an incurable affection, and resort to the injection of pilocarpine and such-like expedients, which is merely waste of ingenuity.

Case.—A. B., æt. 14, was admitted into the Glasgow Ophthalmic Institution in May, 1882, for detachment of the retina of the right eye. The boy appeared healthy; no history of previous ailments, although he looks rather pale; he enjoyed perfectly good sight until within six months ago, when it was noticed that the right eye suffered from convergent strabismus; and about April last, the school-master began to complain that the boy held his book very close to one eye and his head twisted in that direction. On examination that eye was found rather deficient in sight;—and in the beginning of May the failure of vision terminated in almost total blindness. Ophthalmoscopic examination on admission revealed detachment of the retina, limited to the lower and outer part; while the optic disc and the upper and inner segment of the fundus were quite visible. This apparently healthy part of the fundus, although not detached, presented a fine sub-retinal infiltration: this condition will account for the almost complete abolition of sight. He could see the shadow of a finger moved downwards and inwards, but to the upper and outer side of the field he could not distinguish even shadows, or point out the movements of a burning taper. As the abolition of sight was out of all proportion to the retinal detachment, Dr. Wolfe considered the case as affording little encouragement for surgical interference. The boy was brought back again in July, his parents desiring that something should be tried. Reconsidering the matter, and reasoning that perhaps the retinal infiltration and abolition of sight of that portion may merely be the result of effusion in the other part, he decided to operate in his usual manner.

Operation.—Patient being put under the influence of chloroform, a speculum introduced between the eyelids, the eyeball was fixed by forceps, and rotated upwards and inwards; a vertical slit was made with scissors into the conjunctiva and sub-conjunctival tissue, laying bare the sclerotic below the equator at its anterior aspect. The lips of the wound were then held apart by two small strabismus hooks; the eyeball was steadily maintained in that position to prevent the exposed portion of the sclerotic from shifting. The narrow sclerotomy was introduced parallel with the sclerotic into the effusion, and on withdrawing it, pressed upon the lower lip of the scleral wound, when yellow serum gushed out. The lips of the external wound were brought together by a fine silk ligature. The eye was closed by means of strips of adhesive plaster,

covered with dry lint, and secured by an immovable bandage.

On the 4th day the dressing was removed, the eye opened, and the ligature removed on the 5th day. Sight was improved to the extent that he could count fingers in every direction.

On the 7th day he could see everything in the house; and when the left eye is closed he can move about the house without assistance, but he cannot read print.—Tl.

14th day after operation.—He reads No. 20 of Jaeger with perfect ease; and very little mark of an operation visible. Ophthalmoscope shows clear definition of the disc, and an improved condition of the retina, with scarcely any retinal detachment visible. The perimeter shows the existence of scotoma at the site of the incision.

24th day, Tn= Improvement of vision maintained.

History of the Operation.—The first successful case in which Dr. Wolfe adopted this operation for detachment of the retina was recorded in the *Lancet*, October 12th, 1878, as an original operation; but in his work on "Diseases and Injuries of the Eye," he gives the credit to Prof. Hirschberg of having published the first successful case in the *Centralblatt* unknown to him. In a letter, however, which he has received from Prof. Sattler, of Erlangen, that eminent ophthalmologist states that "among the German surgeons, to Prof. A. Graefe is due the credit of having first performed the operation, in the summer of 1876, and published it in the beginning of 1877." He further states: "There can be no doubt that you hit upon the same idea totally independent of Prof. A. Graefe, as it often occurs with eminent surgeons of different countries." It may be remarked, however, that the operation as performed by Dr. Wolfe differs materially from Graefe's operation; for whilst Graefe simply rotates the eyeball and makes the puncture through conjunctiva, fibrous capsule, and other soft parts, and allows the serum to well under the conjunctiva to be absorbed, Dr. Wolfe denudes the sclerotic and withdraws the serum entirely. The one is an operation done in the dark under cover, and may entirely prove a miscarriage; the other is done in open light, and can be managed with more precision. Dr. Wolfe considers the difference of great importance to the ultimate success. The case is more worthy of record inasmuch as I am not aware that the operation has been practised in this country by any other surgeon; but it may be, perhaps, because surgeons have preferred to adopt Graefe's method, without being able to report favourably, in consequence of which, it has never become more general. I may also remark that, apart altogether from the successful results obtained, considering the innocuity of the operation, the question is—whether it should not be resorted to in order to relieve the deep structures from the incumbrance of serous infiltration which may have a deleterious influence upon the healthy eye? If there be any truth in the modern opinion that in cases of injuries sympathetic inflammation is caused by the migration of germs along the course of the optic nerve, may not organisms be developed from the effused serum and thus affect the healthy eye?

Since the above report was sent to press we have had another successful case of the same kind, which will be reported in a forthcoming number.

Department of Lunacy.

DISEASE OF SEXUAL ORGANS IN THE INSANE.

DR. S. DANIELS, a Russian physician, contributes an article to the *Deutsch. Med. Zeitung* on this moot question. He has been making researches into the relative frequency of sexual disorders in the insane.

Two hundred insane females were subjected to a gynaecological examination, when the following results were obtained:—

1. In 162 (nearly 80 per cent.) some form of disease of the sexual organs was met with.

2. Of 140 women who menstruated, their ages ranging from 15 to 42 years, only 20 were found who were entirely free from disorder of some kind or other.

3. Of 60 women who had ceased menstruating, from 42 to 75 years of age, gynaecological disease was found in 18.

4. Amongst the women who were menstruating, acute and chronic forms of endometritis of the whole organ prevailed in 40, of the cervix in 22; chronic inflammation of the body in 116 cases; of the cervix, 8 cases; complicated by erosions of the os in 12 cases; irregular menstruation, 28 cases. Then follow displacements, acute and chronic disorders of the ovaries and neighbouring organs. Vaginal catarrh was more rare (7 cases); of the vulva, 4. There were 4 cases of rupture of perineum, and 1 case each of the following—viz., ovarian cyst, fibroma uteri, and papilloma urethrae.

5. Amongst the non-menstruating women (excluding cases of senile atrophy), chronic inflammations of the uterus were specially noticeable (4 cases); old perineal ruptures, 4 cases; and, finally, so-called senile endometritis.

From the "mental" point of view, the cases might be classified as follows:—(a) Menstruating: Idiocy, 1; epilepsy, with insanity, 15; hysteria, 11; progressive paralysis, 14; primary madness, 31; melancholia, 25; secondary imbecility, 10; puerperal melancholia, 5; mania, 18; alcoholism, 2; puerperal mania, 8. (b) Non-menstruating: Progressive paralysis, 10; melancholia, 10; primary insanity, 9; alcoholism, 3; secondary imbecility, 28.

Of those that were menstruating, 31 were virgins, 41 sterile, 68 had born children—38 one child each, and 30 more than one. Of those not menstruating, 2 were virgins, 14 sterile, 44 multipara. Of these, 9 had had from 8 to 12 labours each.

These results show that the complication of mental disease with sexual disorders is a frequent occurrence that demands the greatest attention on the part of clinicians.

[Many people will think—and, perhaps, not improperly—that the Russian physician permitted a too eager spirit of inquiry to get the master of him, and carry him into fields it were better not to have entered. It is to be hoped that the time is yet far distant when the enthusiastic gynaecologist in our own country will subject females who cannot, from the nature of their complaint, give their consent, to examinations from which they cannot possibly derive any benefit themselves, and with which no pretension of treatment is associated.—TRANSLATOR.]

PROFESSOR GAIRDNER ON THE RELATIONS OF SPECIALISM WITH GENERAL MEDICINE.

THE thirty-seventh annual general meeting of the Medico-Psychological Association was held in the Hall of the Faculty of Physicians and Surgeons, Glasgow, on the 2nd inst. Dr. Hack Tuke, the retiring president, vacated the chair, which was taken by Professor Gairdner, the president for the year. Professor Gairdner having thanked the members for the honour done him, proceeded to say that the duty which stood before him—the question he had asked himself—was this: What could he say to them in the necessarily limited time at his disposal which would in any degree touch a responsive chord in their minds, to show that they, as being what the world called specialists, and he, as a professor of medicine in general, had in reality but one aim in view, and that they were guided by one and the same scientific method and doctrine in dealing with the unsound mind on the one hand, and the unsound body on the other. To justify their belief that they were all one profession, they must in the end be able to show that they worked upon the same lines, with similar instruments both of research and of cure; that they

aimed, not at separating and dissecting the complex functions which constituted human nature into a bodily and a mental part; but that each of them in his own separate sphere was dealing with humanity as a whole, in which body and mind were inextricably interwoven. That they believed to be the true philosophy of the healing art in all its separate department, and whoever even for a moment forgot this had already gone some steps on the fatal road that led to unworthy views of his profession—in short, to mere empiricism. He had, in other words, already adopted a position which, when biased by low moral proclivities and the love of money, soon gave place to quackery. The members of the profession were not open to these base suggestions. It was a characteristic of their work that it had become a specialism, not through individual impulses, or for individual gain, but through circumstances in the nature of the work itself, making it in some degree a public function, and thus guarding it in

large measure from becoming a prey to the vampires whose only business with the medical art was to drain its lifeblood for their own particular use and advantage. They were, however, by no means secure against the tendency inherent in all specialisms to dissociate their cultivators from the general stream of tendency, so to speak, and from the actual facts and principles of the healing art in general. It would be by no means surprising were the treatment of the insane to become a specialism wholly divorced from the progress of medical science and medical art, and it was not too much to say that, whatever else was intended by it, the honour they had done him in placing him in the chair was a distinct recognition of the fact that such divorce was possible, and that they would regard it as a misfortune. While they were devoted to the treatment of the insane they had not ceased to be physicians. Dr. Gairdner went on to speak briefly on some of the relations existing between their specialism and the healing art in general. He remarked that he was not at all wedded to any theory of the association of "mind and brain," or of "body and mind," but he held it to be an unquestionable truth that the analogies, and even the laws, of bodily functions shed an immense amount of light on the study of mental diseases, and *vice versa*. In seeking for evidence of this position, he would go at once to what must be regarded as one of the most brilliant advances of the healing art that had taken place within the compass of two generations, or even of a century, the improved, or, as it was often called by way of contrast, the modern system of treatment of the insane. Taking origin in the last decade of the eighteenth century, this might be said to culminate in the present decade of the nineteenth in such a large pauper asylum as Woodilee, which might be specially commended to their notice as under the care and superintendence of their Scotch secretary, Dr. Rutherford. What was the essential basis of this great and beneficent change—or, rather, let them say, what was the common principle, speaking of it from the physiological and medical point of view, illustrated in all the changes that made the difference between the Bedlam of 1815 and the Bedlam of 1882. It was that in the whole pathology of disease the normal function must be held to underlie the abnormal, and that in the cure and treatment of disease accordingly the sound elements still remaining must be carefully respected, strengthened, and built up again if possible, in all cases, however, anxiously tended and nursed; the sound man within the unsound, the sane man within the insane, being supported and buttressed as it were so as to reduce to a minimum the injury caused by the disease. This principle he held to be, in the largest sense of the word, a humane one, and that it was carefully grounded on the

consideration of human nature as a whole, and not taken piecemeal. Being so, it was humane in the narrower sense that it did not allow of any amount of disease and action or function, whether of mind or of body, depriving the sick man of any of the privileges of our common humanity which could in the nature of the case be accorded to him.

THE LUNACY LAWS AMENDMENT BILL.

THE MONTROSE ASYLUM AND INFIRMARY.

At the meeting of the Board, held on the 1st inst., the clerk read the report of a deputation appointed to wait on the Lord Advocate and other members of the Government in reference to the Lunacy Laws Amendment Bill. His lordship said that the County Prison Boards having been abolished by the Act of 1877, it was not considered desirable to revive the boards in order merely to exercise this function of applying to the General Board for the division of a lunacy district. To have conferred the restored power on the Commissioners of Supply and the Magistrates of burghs would have made the Act a dead letter. After the explanations of the deputation, the Lord Advocate stated that he saw no other course at present but to withdraw the Bill for the present session.

THE BRITISH MEDICAL ASSOCIATION AT WORCESTER.

FIFTIETH ANNUAL MEETING.

THE semi-centenary meeting of the Association which was brought to a termination on Saturday last may be classed with those assemblies which were successful rather than brilliant. It could not, of course, be expected that a meeting of the Association held in a cathedral town in a somewhat remote part of the kingdom would compete in interest with the gatherings which have taken place in the great capitals of the country, and whenever cities like Worcester come to be the entertainers of the Association, one cannot but feel that the willing efforts and pecuniary resources of the local members of the profession and civic authorities must necessarily be somewhat overtaxed by the attempt to extend a lavish hospitality to the 500 or 600 members of the Association who attend, with their sometimes unreasonably large *entourage* of wives, and frequently immature children.

The recent meeting had, however, three very special elements of attraction and success. *Imprimis*, it was the fiftieth anniversary of the founding of the institution, and the occasion would, therefore, very probably compel the presence of the office-holders of the Association, and of those enthusiastic in its administration. *Secondly*.—The meeting took place under the special auspices of Mr. Hastings, M.P. for the City of Worcester, whose invitation to the profession to come and do honour to the memory of his revered father—the Founder of the Association—could not well be declined. *Lastly*.—The weather condescended to join in the general jubilee, and ably assisted in receiving the visitors and in decking the charming old city of Worcester in its very best holiday garb.

These circumstances all conducing, as we have said, to make successful, if not brilliant, the Association gathering for 1882, and we heartily congratulate the reception committee upon the favourable issue of their generous and hospitable labours.

The number of persons who took out tickets, members and non-members, was very close on 600.

The first day of meeting (Tuesday, 8th) was occupied, as is usual in the "gathering of the clans," in the issue of tickets, allocation of lodgings, and interchange of greetings, and no other business was done until 8 p.m., if we may except a special service and sermon in the Cathedral, and a special dinner given by the Mayor to the officers of the Association.

In the evening, however, the official business commenced, and the proceedings proved both interesting and important. The usual vote of thanks to Dr. Barrow, of Ryde, the outgoing President, having been passed, Dr. Strange, the host of the present meeting, was duly installed, and delivered his inaugural address, in which he drew an amusing and interesting parallel between the doctor of fifty years ago and to-day, pointing out with much force how valuable the medical journalism which had its birth and growth within that period had proved, by raising the provincial surgeon almost to the level of his metropolitan *confrère* as regards social status and scientific education.

FINANCE.

The Report of Council, which was next presented, showed an income of over £16,500, with increasing revenue, but also with an increase of £600 in expenditure, besides a lawyer's bill for over £1,000 for the Cork Pilocarpine libel case. The Association now numbers 9,563 members.

We are amused to observe that the Council takes much honour to itself for having, in the years 1880 and 1881, followed the example of cutting the edges of the journal, which the *Medical Press and Circular* showed it some years ago, and which the editor then sneered at, as being possible only for small journals, and not to be thought of by those of leviathan circulation.

HOMŒOPATHY.

The storm which was raised by the deplorable advocacy of homœopathy by the official speakers of the Association last year, at Ryde, made itself felt on Tuesday evening as a gale sufficiently strong to ruffle the surface, and indicate "how the wind blows" on this subject amongst the members of the Association. The profession, as our readers know, had spoken out on the subject with so loud a voice that the Council was obliged, a little hesitatingly, to repudiate the fraternisation with homœopaths recommended by Dr. Bristowe and Mr. Hutchinson at Ryde. The Council now expresses itself as follows:—

"A memorial was presented demanding the expulsion of a member on the ground of his public profession of homœopathy.

"To this extreme measure the Committee of Council could not accede. As far as is possible, they have rigidly closed the door of entrance, and have made it impossible for a professing homœopath to enter the Association through election by the Committee of Council; and they have called upon the Branches to aid them, by demanding that every name proposed for election shall be inserted in the circular summoning the meeting at which election is sought. Thus both doors of entrance are effectually closed. Against perversion to homœopathy after admission, they are at present powerless, except by the expulsion of the offender; and this, under present circumstances, they consider undesirable—first, because they hold that such a course would be beneath the dignity of the members of a great liberal profession; and, secondly, because it would confer an amount of notoriety which is very undesirable upon those who were expelled. The Committee of Council courts a full expression of opinion on the part of the whole Association; and, if it should determine that the profession or practice of homœopathy shall—*ipso facto*—disqualify from membership, then the unwitting election of a homœopath would thereby be rendered null, and perversion after election would imply the voluntary cessation of membership."

The Council, therefore, has made new rules, that—

"1. There shall be a standing notice in the *Journal* every

week of the meetings of the Committee of Council; and stating that gentlemen wishing to be elected members of the Association must send in their names *twenty-one days* before the meeting.

"2. That a list of applicants be in the hands of the Committee of Council *fourteen days* before such meeting of the Committee of Council, and that the Branch Secretaries be supplied with *several* copies of the list.

"3. That no member be elected by a Branch unless his name has been inserted in the circular summoning the meeting at which he seeks election."

A considerable section of the Association (with whom we sympathise) consider the course proposed by the Council altogether too mild for the exigencies of the case; and considering that members have obtained admission as scientific physicians who, having turned homœopaths, have still held their membership, and that the Committee of Council had invited "a full expression of opinion on the part of the whole Association as to whether the profession and practice of homœopathy shall *ipso facto* disqualify from membership," Mr. Nelson Hardy, on behalf of that section of the members, moved a rider to the adoption of the report, couched in these identical terms. Upon this amendment the reason for the milk-and-water action of the Committee of Council became manifest, for although that Committee had invited an expression of opinion, some of its leading members did their best to put Mr. Hardy out of Court. The President thought the amendment was not in order, and that "the words put into Mr. Hardy's mouth by the Committee of Council were obscure." Dr. Husband, formerly of York, pooh-poohed the notion of expelling any homœopath, and threatened the Association with the prospect of a lawsuit if it were done. Other members helped to obscure the subject in a legal fog, and eventually (it being stated that the Committee of Council possessed expulsion powers if they pleased to use them) Mr. Hardy's motion was thrown out on a division. The debate has, however, made manifest that if those who despise and detest homœopathy mean to effect their purpose, they must apply the cautery with no hesitating hand to the Committee of Council, and thereby get rid of the party who, while admitting that they have power to deal with homœopaths, are unwilling or afraid to do so. Mr. Hardy and his followers must also organise better next time, and be prepared to put forward a resolution which cannot be shuffled out of on points of law or misconceived as to its meaning.

THE EDITORSHIP.

The attempt of Dr. Milner Fothergill to shake the existing editorial system of the Association, as to which a smart debate had been expected, came to nought, Dr. Fothergill not having been present when called upon to proceed. The cause, to use a legal phrase, was therefore struck out.

RECONSTITUTION OF THE EXECUTIVE.

Dr. Ward Cousins, of Southampton, then moved the following alterations in by-law:—

1. The President of the Association to be an *ex officio* member of the Journal and Finance Committee.
2. The annual retirement of four of the elected members, who shall remain ineligible for re-election for two years.

In hostility to this very reasonable and business-like proposition, Mr. Wheelhouse undertook to illustrate Dr. Cousins' remarks as to the system of breeding in-and-in of the Committee, by arguing at length that the President of the Association has no right to a voice in its management, and that no one can be so desirable a committeeman as he who has accustomed himself to the old groove, and is willing to vote that every future committeeman shall confine himself to the same groove. This ingenious, but some-

what conservative, line of argument did not, however, avail, and the members of the Committee saw the wisdom of falling back upon a committee of inquiry, to which, accordingly, Dr. Ward Cousins' proposal was sent for probable sepulture.

THE SCIENTIFIC ADDRESSES.

We cannot here refer to the Addresses in Medicine and Surgery delivered by Dr. Wade, of Birmingham, and Dr. Stokes, of Dublin, delivered before the general meetings, further than to say that they were both admirably conceived, connected, and commendably brief, and were listened to with well-deserved attention, Mr. Stokes' address in defence of Listerism being considered by those who heard it as the event of the meeting. We give full abstracts of them in our present issue.

THE DROITWICH BRINE BATHS.

On Friday there was an excursion to Droitwich to visit the brine baths there. About 200 members left by special train. The little town was *en fête*. Flags floated everywhere, two triumphal arches spanned the road, and the members walked to the baths through crowds of people, who lined the roadsides. Several enjoyed the plunge bath, and afterwards there was a magnificent luncheon in a large marquee.

TEMPERANCE AT THE ASSOCIATION.

Each year the members and the interest in the meetings for the promotion of temperance principles appear visibly to increase. A good deal of enthusiasm was manifested at the breakfast given by the Medical Temperance Association on Thursday, and several members—both professed and non-abstainers—spoke warmly in favour of the treatment of disease by the exclusion of alcohol, and the value of abstinence as a moral principle. Among the speakers were Dr. Strange (President), Dr. Carpenter, of Croydon, Dr. Drysdale, Dr. West, Mr. Lennox Browne, Mr. J. Taylor, of London, Dr. Richie, of Leek, and others.

FUTURE MEETINGS.

The Liverpool practitioners, through Dr. Davidson, presented an invitation to the Association to meet there in 1883, and the profession in Belfast, through Dr. John Moore, a similar invitation for Belfast for 1884, both of which were accepted by the meeting with acclamation.

NOTIFICATION OF INFECTIOUS DISEASES.

This subject gave occasion for the final debate in the last general meeting of the Association. It is not necessary for us to recapitulate the history of this question, already so frequently referred to in our columns. It is sufficient to say that the Parliamentary Bills Committee had, notwithstanding frequent representations against the measure by its constituents, pledged itself to a support of the principle of compelling medical practitioners, under penalty of fine and imprisonment, to report all infectious cases to the sanitary authority. The secret of the intentions of the Committee had by the ingenious vagueness of its yearly reports, and the studious silence of the *Journal* on the subject, been so well kept from the members and the profession generally that up to last year few dreamed of the plot which sanitarians had laid for the physician. At Ryde, however, the plan was prematurely exploited by Mr. Michael, Q.C., and thenceforth a storm has been rising in the profession, which we hope and believe will seriously modify the pro-compulsion views of the Parliamentary Bills Committee. The subject was ably brought before the meeting by Dr. Carter, of Liverpool, who moved, "That, in order fairly to test the opinion of the Association on this point, a plebiscite be issued, asking, in some form to be agreed upon, whether the members of the Association do or do not agree to the principle of compulsion on medical men."

Dr. Whittle (Liverpool), in the unavoidable absence of Dr. A. H. Jacob, of Dublin, who had been summoned by telegram to London to give evidence before the Parliamentary Commission on Poor-law Medical Superannuation, seconded, and took the opportunity of presenting a statement of opinion signed by nearly 600 members of the profession, confided to Dr. Jacob.

Dr. Littlejohn (Edinburgh) was opposed to any such plebiscite. He moved as an amendment, "That, in the opinion of all competent sanitary authorities, notification is the indispensable basis of action for arresting the spread of disease, and bearing in mind the satisfactory opinion of those Acts, the meeting decline to withdraw the approval which the Association has repeatedly expressed in favour of urging Parliament to make the notification of infectious diseases compulsory, under such conditions as may appear to be best calculated to protect the public health."

Mr. D. Everitt (Worcester) seconded.

Dr. A. Carpenter (Croydon) said they were all desirous to repress the spread of infectious disease, but could not yet get the duty performed without hanging round their neck a penal clause which a professional brother and a professional rival might put in operation against them. If the penalty were put upon the householder, and the moral responsibility upon the medical man, they would get a better repression of disease.

Mr. G. W. Hastings, M.P., said he thought Dr. Carpenter's suggestion would entail greater hardship upon medical men than the system now complained of.

Dr. Carter's resolution in favour of a plebiscite was then put, and declared lost; but when Dr. Littlejohn's compulsion amendment was put from the chair, a further amendment was moved by Dr. Mahomed (London), "That this meeting earnestly desires the compulsory notification of infectious disease, but wishes to express the opinion that the compulsion to notify should be placed upon the householder as his duty as a citizen, and not upon the doctor."

Mr. Husband (York) seconded.

This amendment was carried by a large majority, and, having become the substantive motion, was adopted.

We shall give a report of these important proceedings in our next issue. Meanwhile, we would say that it must be obvious that the voice of the Association is overwhelmingly against compulsory notification by the physician, so much so that it would not approve the suggestion of Dr. Carter for a preliminary plebiscite, and, as we are satisfied that there can be no doubt as to the feeling of the profession at large, we agree in the objection to a plebiscite thus affirmed. It is much regretted that Parliamentary duties detained Dr. Jacob in London, and prevented his stating to the Association, as he could have done, the firm determination of the profession in Ireland to refuse the duty of compulsory notification on any terms.

LEGISLATION FOR HABITUAL DRUNKARDS.

Dr. Alfred Carpenter read the following report of the Committee appointed to obtain Restrictive Legislation for Habitual Drunkards, which was seconded by Dr. Drysdale, and adopted:—

"During the past year the Committee have used every effort to further the practical operation of the provisions of the Habitual Drunkards' Act, 1879. The independent committee which sprang from the joint action of your Association, the Social Science Association, and the Society for the Promotion of Legislation for the Control and Cure of Habitual Drunkards, has merged into the Dalrymple Home Association, a society limited by guarantee, but with power to omit the word 'limited' from its title, under a licence from the Board of Trade, as being a philanthropic Association. The Dalrymple Home is under the patronage of the Arch-

bishop of Canterbury, the Duke of Westminster, Earl Shaftesbury, Sir Thomas Watson, Sir Henry Thompson, Dr. Andrew Clark, Dr. B. W. Richardson, F.R.S., Dr. Cameron, M.P., Dr. Farquharson, M.P., and other representative men. A large number of sites have been examined, and negotiations are actively going on, so that it is hoped that the Dalrymple Home for Inebriates will shortly be opened in a healthy suburb of London. It is intended to apply for a licence for the compulsory detention of such inmates as may elect to come under the provisions of the Act, and it is proposed to receive habitual male drunkards at a considerably lower rate than they can now be admitted at in similar private institutions. Feeling deeply the importance of this praiseworthy attempt to carry out the purpose of a beneficent though very imperfect Act, your Committee earnestly desire to impress on the members of your Association the urgent need for ample financial and other support. The Habitual Drunkards' Act will expire in seven years, but your Committee trust that, under the curative influences of the Dalrymple Home, the cure of a few typical cases of habitual drunkenness will secure from the Legislature fuller and more satisfactory compulsory powers. The Committee have issued a second circular to Boards of Guardians, asking for an expression of opinion on the propriety of guardians having the power (if they choose to exercise it) of detaining habitual drunkards in workhouses, of which they are frequently inmates for the purpose of recovering from the effects of their excesses. To the first circular a number of favourable replies were received; and the responses already received to the last circular indicate a yet wider and fuller assent to the views of your Association. Your Committee would strongly urge members of the Association to bring all their influence to bear on the Boards of Guardians in their respective districts. The replies are daily coming in, and the very general approval of your Committee's views by parochial authorities affords good ground for encouragement."

THOUGHTS SUGGESTED BY THE MEETING.

There are one or two minor matters respecting which we think it well to make remark in concluding our analysis. Why will gentlemen—however senior and respected they may be—insist on dosing their audiences with endless congratulations and self-glorifications when the impatience of the hearers is made manifest by overwhelming interruptions? A painful instance of the *vis inertiae* of the human tongue was shown at the luncheon given for the presentation of the bust of Sir Charles Hastings. On that occasion an old and much-esteemed officer of the Association indulged himself (and no one else) with a speech of about half an hour, the purport of which no one could even guess, considering that the gentleman's voice was altogether overwhelmed by coughing, "oh! oh!" shuffling of feet, and various other manifestations of displeasure. Such "exuberance of verbosity" is intolerably dreary, and ought not to be repeated.

Why, again, will certain members make the meetings of the Association a school-feast for their juvenile families? Is it reasonable for gentlemen who have been invited together for interchange of professional opinions and hospitalities to encumber the generosity of their hosts with luncheons and excursion accommodation for their boys and girls? Surely it is not reasonable, and ought not to be tolerated; and if these hints do not suffice, we think the Association must limit by rule the number of amusement tickets issued to members.

THE University of Würzburg celebrates its 300th anniversary this year (its 6th jubilee). In honour of this event, honorary distinctions will be conferred—sparingly. Four gentlemen—Prof. Quincke, of Heidelberg, Prof. Clausius, of Bonn, Prof. Charcot, of Paris, and Herr Bdaumüller, the Vienna bookseller—are named as likely recipients of honorary M.D. degrees.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 16, 1882.

THE ADDRESSES AT THE JUBILEE OF THE BRITISH MEDICAL ASSOCIATION.

As though in support of the position we sought to maintain in the last number of this journal respecting the real aims of the British Medical Association, and the necessity that exists for more united action on its part, the President's address at the annual meeting just concluded bears directly on the point to which we specially directed attention. Dr. Strange has accurately appreciated the weakness of the great body over which he has been called to preside, and we may perhaps anticipate that his endorsement of statements previously uttered will go some way to ensure their being duly considered and acted on. Certain it is, however, that the future of the Association will very much be influenced by the extent to which such admonitions are regarded, and the following extract from the address referred to will show that Dr. Strange at any rate is alive to the importance of the matter:—

"Let me record my own individual opinion, founded upon much reflection upon our past and present condition, that the power of combination which the British Medical Association possesses within itself has not hitherto been developed to anything like its full and beneficial extent. Its power to elevate the moral and social elements of our character in the future appears to me to be as great as that it has already exhibited in enhancing our intellectual status. In point of fact, the second fundamental *raison d'être* of our existence is now only surging below the surface. Great questions are coming on for solution. May they be solved in accord-

ance with the motto of our Association laid down for all time by Charles Hastings and his associates. When that consummation shall have come to pass—when self-interest and self-assertion shall have given place to brotherly co-operation in well-doing, and to Christian charity and courteous deference to one another, then, and only then, will the British Medical Association have fulfilled its mission."

In other places, also, the President of the Association gave evidence of the care with which he had striven to discover the lines along which he might most hopefully direct its future labours. Commencing with a sketch of the period from 1830 to 1840, when an impetus was given to medicine, to the force of which the present position of the profession is in great part traceable, he proceeded to demonstrate what may be called the virtues of medical men, and the shortcomings which injuriously affect the well-being of the whole body of the profession. As a means of bringing about improvements which have again and again been urged in these columns, but which it is all but hopeless to anticipate at present, Dr. Strange proposes that a consultative court shall be created, which may act as a "High Court of Equity and Ethics," and the members of which shall be chosen by and from the great body of medical men. Whether the choice of these representatives shall rest directly with the profession, or in the hands of committees, he is not quite distinct in his utterances, but that he would be ready to accept a plan admitting every practitioner to have a voice in the election, is to be gathered from his declaration that, though "not very fond of universal suffrage, he would not hesitate to submit himself to the arbitrament of a tribunal so constituted;" that is, a tribunal half of whose members were elected at the annual meetings of the Association, and the remainder by its Council. In principle, the proposition is a good one; but in execution it will need to be much amended from Dr. Strange's idea ere it will appeal to the sympathy of medical men as a whole. The action of the Council of the Association hardly carries with it so general acceptance that it can be said to reflect the voice of professional opinion in this country; nor do certain of its decisions encourage unbounded trust in it as at present constituted. But apart from this the suggestions contained in the presidential address delivered by Dr. Strange are worthy to receive, and doubtless will obtain, serious and careful consideration.

Dr. W. F. Wade's Address in Medicine was what those who knew his ample powers expected it would be—a masterly and eloquent composition. He took as a theme the influence of error, and by such examples of erroneous practice as blood-letting under all circumstances as a universal remedy, the employment of alcohol as a specific in acute diseases, &c., illustrated the important advances made in the science of medicine as a result of studious investigation prompted in the minds of the pioneers of rational physic. Marshall Hall's experiments in connection with blood-letting naturally offered an opportunity for pardonable reference to the value of, and influence exerted by, the scientific method of inquiry, and the following sentence taken from this part of Dr. Wade's address will be likely to attract some further attention. Speaking of the motives which

were at work to cause Hall to resort to the experiments on animals which formed the basis of his conclusions against the practice of blood-letting formerly so commonly adopted, he remarked:—"But it is impossible to decide, after the event, what amount of evidence ought to have been sufficient to fashion and consolidate into a coherent and shapely form the flocculent masses of colloidal truth floating hither and thither in the mind of a discoverer."

On the subject of alcohol in disease Dr. Wade dilates at some length, and combats Todd's views as to its universal value in inflammation. He concludes that "the medical mind never has ceased, and probably never will, to hanker after specifics," and argues as to the false security likely to be engendered by the possession of a reputed specific. In this, as in all that fell from his lips, he is an eminently practical adviser, but the advice tendered is, nevertheless, couched in language that has borrowed such eloquence as makes it most commendable; and the concluding words of his address will appeal to all, it is to be hoped, to cause them to fulfil, each in his way, the duties that fall to every earnest practitioner:—"To few only is it given to extend the landmarks of science, or to reclaim the waste lands of ignorance. But to each one is given the power to cultivate and utilise those which have been reclaimed. To each one it is given to make the practice of medicine more rational, more common-sense, and therefore more truly scientific; to render more rare in the future such dark blots as we have regretfully recognised in the past."

The Address in Surgery delivered by Mr. Stokes will lose none of its interest with the lapse of time. From the deservedly high reputation its author enjoys in the profession, the opinions he utters, though scarcely intended to carry the force of opinions, will, nevertheless, be received as authoritative statements, and no better service could have been rendered by him in the position he occupied than that he has done. Mr. Stokes briefly dealt, at the outset of his speech, with the subject of the education of medical students, his recent experiences as Visitor of Examinations for the General Medical Council peculiarly fitting him for the task. He would like to witness "a consolidation of the great medical and surgical teaching power that exists in our metropolitan centres, but which, owing to the multiplicity of separate schools in them, is, to a great extent, lost to the profession and the public." He also favours "heartily and loyal co-operation with the Universities, the medical and surgical corporations of the United Kingdom, and the General Medical Council, to raise the standard of Arts education for all joining our profession by establishing conjointly an examination in Arts which every one, except those with University degrees, should pass previous to commencing the study of medicine." In this opinion he has been strengthened through having frequently observed candidates for diplomas whose general and scientific culture was far below what any one joining the profession of medicine ought to exhibit.

The greater part of the address, however, was taken up with a discussion of anæsthetics, antiseptics, and osteogenesis. In reference to Listerism, Mr. Stokes

exposed the hollow nature of the opposition raised against it by Mr. Savory and his school, whose practice he showed to be eminently antiseptic in the real meaning of the term, and to be based on the principles which guide the Listerian treatment. The influence exercised by germs in inflammatory processes was considered in connection with Dr. Burdon Sanderson's recent lectures, and Mr. Stokes' own experience in antiseptic surgery was demonstrated by him in a way to carry earnest conviction of the triumphs he modestly related. His remarks on osteogenetic operations will likewise be read with great interest, but we may refer to the address published in full in another column for the details.

IRISH PRELIMINARY EXAMINATIONS.

THE recommendation adopted for the last two or three years by the General Medical Council that all examinations of medical students in general education should be left to the Universities has induced the London College of Surgeons to discontinue its "preliminary," but in Ireland the qualifying bodies have not seen their way to comply with the suggestion. In Ireland the licensing bodies are also teaching bodies, and it has been found necessary by them to hold on to their preliminary examination, lest—by handing over the student to a rival institution just at the moment when his choice of a qualification has been made—he might remain for medical study and for his licence at the institution where his first examination was undergone. The last Session of the General Medical Council has in great measure, but not altogether, removed this difficulty, because it has been decided that the Irish intermediate examinations shall be recognised in every case in which the student can produce a "pass" in all the subjects which the Medical Council requires. The Council of the Irish College of Surgeons has agreed to accept this extent of intermediate examination, and also the matriculation examination of the Royal Irish University, as equivalent to their own "preliminary;" and thus two additional gates of entry for the Irish student have been thrown open. But there are sufficient reasons why the College cannot discontinue its "preliminary," because none of these substituted examinations meet the necessities of all classes of medical students. The public entrance examination of Dublin University, for instance, costs £15, and is, therefore, out of reach of all save those who mean to go forward to an arts' degree. The Royal Irish University arts course for medical students consists of two examinations, with an intervening year. The intermediate examinations will, no doubt, be taken by a large percentage of the medical students of the future, because they can be prepared for and passed without leaving home, and at any age up to 19; but they will not suit *all* students, and, therefore, an examination must be maintained for those who cannot comply with the intermediate regulations. In the first place, it is not possible for a student, under any circumstances, to pass the intermediate at a later age than 19; and we know that many come to the profession at much later

periods than this. Again; these examinations are held uniformly in June—a time of year not at all convenient for the student who commences medical study in November. Lastly, the intermediate examinations do not include all the required subjects. Mechanics is not a part of their programme, and until that subject is either struck out of the requirements for medical students, or transferred to the preliminary scientific examination of the first professional year, or else examined in by the Intermediate Board, the popular educational test of Ireland cannot fully supply the wants of medical students. We have no doubt a way will be found of adjusting this difficulty, and—we think—the sooner the better; for we share the desire that in Ireland, as elsewhere, an efficient educational test may be provided which will be entirely independent of teaching and licensing interests. Such a test is of cardinal importance to the social status of our profession, which has suffered much in character from the crass ignorance of some of its members in the rudiments of a gentleman's education.

Notes on Current Topics.

The Poisoning Incident at Inverness.

REFERENCE has several times been made in these columns to a remarkable epidemic of poisoning at Inverness which occurred last Good Friday. It will be remembered that the effects were traced as being caused by buns purchased from a certain baker, only those supplied by him having been attacked with the symptoms from which all eating the buns from this particular batch suffered. Subsequent analysis on the spot of the buns remaining, and of the flour employed in making them, revealed no poison to account for the outbreak; and now a report on the subject has been issued by the Crown analyst. According to this, no mineral poison has been found in anything submitted to analysis, but there *has* been discovered an unknown irritant alkaloid in the buns. These, however, were spiced; and loaves made from the same batch of dough, but unspiced, were eaten with impunity, while the buns alone produced ill-consequences, so that the conclusion is irresistible that the poisonous agent is in the spice itself. It remains to determine this with accuracy.

The late President's Wound.

THE controversy respecting the treatment to which the late President of the United States was submitted by the surgeons who attended him during his illness is likely to be reopened by the publication of a lecture which Prof. Esmarch delivered some time ago at Kiel. This address was devoted to proving that under appropriate treatment the wound inflicted on President Garfield would not have been attended with a fatal termination, which its author insists was mainly attributable to imperfect antisepticism. Esmarch considers that the example afforded by Langenbeck's treatment of the German Emperor after the attack on his life should have been followed, and no attempt made to extract the bullet. The wound was in itself, he infers, by no means mortal, and under favourable circumstances he thinks the

President might have been at this moment a living man. No one, of course, could fail to recognise the great importance attaching to any expression of opinion from Prof. Esmarch on a question of surgery; but it may be nevertheless questioned whether he showed a wise discretion in not only lecturing on a subject by treating which he must necessarily impeach a professional brother, but also by publishing the lecture subsequently. Moreover, the matter is one that may very well claim to require consideration apart from the anatomical details, in the light of which alone those not present at the case can have any knowledge of it; and on this ground, too, the expression of adverse beliefs ought to be made in the most guarded fashion, especially when coming from so eminent an authority as Prof. Esmarch. We may well doubt whether real science is not at least as much injured as assisted onwards by such proceedings.

The Government Annuities and Insurance Bill.

WHY the Postmaster-General should have wished to try so dangerous an experiment as that of accepting, without a medical examination or certificate, those who may desire to avail themselves of the advantages he is about to offer in the Government Annuities and Insurance Bill, we are at a loss to conceive. We are glad to find that Mr. Torrens has given notice of his intention to move an amendment, to the effect that no life be insured or annuity granted without a medical examination.

Tuberculosis.

DR. KAMMERER, Imperial Health Officer to the city of Vienna, has published an important address to the magistrates of that city on the dangers which threaten the health and life of the population, through animals affected with tuberculosis. The victims are insidiously struck down, says Dr. Kammerer, through two of the most important articles of daily diet—milk and meat. The milk of cows with tuberculosis acts as an unconscious inoculation upon adults and children who partake of it, and in the case of the latter the seed of tuberculosis is being imperceptibly sown amongst thousands in the great towns. Dr. Kammerer regards infection by this channel as being quite as fruitful a source of the disease amongst the young as hereditary taint, to which it is usually traced. He regards it as exceedingly doubtful whether boiling or roasting ever can effectually eradicate the germs of infection in the flesh of tuberculous animals.

Another Alpine Disaster.

LAST week another painful accident occurred in Switzerland, leading to the death of an English student of medicine, Mr. Penhall, of St. Bartholomew's Hospital, and the guide accompanying him. Mr. Penhall was the son of Dr. J. T. Penhall, of St. Leonards-on-Sea, with whom general sympathy will be felt at the terrible misfortune which thus deprives him of a child and the profession of a most promising future member. Coming so soon after the recent disaster which befell the late Prof. Balfour, this accident may well arouse anxiety in the minds of those who are accustomed to seek relaxation and healthy exer-

cise in the Swiss mountains. Unlike the spot at which Prof. Balfour lost his life, however, the scene of Mr. Penhall's death was not regarded as unusually dangerous, the descent of an accumulation of snow having led to the fatality. The question will, notwithstanding this, be a good deal debated whether the risks encountered by amateur mountaineers are not more than enough to counterbalance the advantages they enjoy. It is unquestionable that fully equivalent health-giving exercise can be obtained elsewhere without the element of danger which ever accompanies it in the Alps, and it may well be considered whether they are not wiser who avoid the scenes of such terrible misfortunes. In order to breathe the atmosphere of elevated regions it is by no means essential that life risks should be run, and in spite of the temptations to incur such risks, it can only be an act of indiscretion that will face them after the warnings supplied by recent events.

Death of Professor Leith Adams.

THERE died last week, in Professor Andrew Leith Adams, a member of the profession who was less known in medical circles than in the world of science, where he attained most honourable distinction. Prof. Adams graduated M.B. at Aberdeen in 1843, and after seeing service in the Army Medical Department, retired on half-pay with the rank of Deputy Surgeon-General. His devotion to, and work in connection with natural history procured him the Professorship of Zoology in the Royal School of Science at Dublin, which he resigned to proceed to Cork, as Professor of Natural History there, in 1878. He was a Fellow of the Royal and the Geological Societies, Master of Arts of Aberdeen University, and Licentiate of the Royal College of Surgeons of Edinburgh. As an author he is probably best known through his "Wanderings of a Naturalist in India;" but the Army Medical Reports, and some of the medical journals, contain several valuable contributions on professional subjects from his pen.

Infant Mortality in Workhouses.

THE following particulars throw some light on the cause of the high infant mortality in some workhouses:—At an inquest held at the Halifax Workhouse on Thursday last, before Mr. Barstow, coroner, on the body of an infant three months old, daughter of Bridget Hackett, a single woman stated to be of dubious occupation and character, Mr. T. M. Dolan, F.R.C.S. Ed., said he saw the child first on Sunday, and told the mother that it was very ill. He prescribed for it, and the next morning saw it again. It was then in a dying state, and full of sores from filth. He advised its being taken to the workhouse. Mr. Dolan, in the course of examination, complained of the number of children brought to the workhouse in a dying state, of whose deaths they had to certify the causes. This state of things resulted in the authorities at the house being credited with the responsibility for the large number of infant deaths which occurred. If his directions to the mother in the present case had been properly obeyed the child would have had a chance of getting better. The cause of death was inflammation of the lungs, and a verdict was returned in

accordance with the medical testimony. After severely censuring the mother for her inhuman conduct, the Coroner added that both the guardians and the police authorities were determined to keep a watchful eye on this class of cases, which in many instances amounted to little short of wilful murder.

Treatment of Angina Pectoris.

DR. A. MÜLBERGER, of Herrenalt, who had observed that a young man, the subject of angina pectoris, instinctively pressed his chest violently against the edge of a table, or his closed fists against the cardiac region, imitated this instinctive method of obtaining relief by passing his left arm round his patient's chest, and firmly rubbing the cardiac region with the fist of the right hand, varied at short intervals by quick pushes against the heart.

He believes that in concussion we have an excellent means of keeping in check the violence and duration of the steno-cardiac attacks. He further notes that kneading and rubbing have long been tried and approved remedies against muscular cramp, and that as angina pectoris is nothing more or less than cramp of the cardiac muscle, it seemed to him likely a similar result would be obtained in parallel cases by the like means.

He finally sounds a note of not unheeded warning in the *Deutsch. Med. Zeitung* against the too bold use of remedies in this affection, and we may add in others also, and recalls the case of an elderly medical man who was relieved of his angina only to die of the morphia that procured the relief.

Philanthropic Inconsistency.

UNDER the head of cruelty to animals, an exchange prints the recent bequests in a Philadelphia will, leaving 1,000 dollars to the Society for the Prevention of Cruelty to Animals, and 15,000 dollars to the managers of a Women's Hospital, on condition that they for ever keep out all unfortunate girls from the obstetrical wards.

An Accessory Placenta.

A WOMAN recently gave birth at the Paris Maternité to a living child, head presentation. Fifteen minutes later, the placenta appeared at the vulva, and yet could not be immediately removed. While the midwife was tying a ligature back of the portion expelled, a hæmorrhage took place, and a second placenta was expelled, weighing 40 grams, and the first one 410. The two were formed by a membrane and a few ramifications of blood-vessels.

A New Material for Ligatures.

IN the June number of the *Archives of Medicine* we find a contribution by Dr. John A. Wyeth, of New York, on the above subject. The success attending the employment of ligatures made of animal tissues made Dr. Wyeth look for something smoother and stronger than anything yet introduced, and this he thinks he has found in carbolised nerves. He narrates a case in which he tied the common carotid artery, using as a ligature the freshly cut, carbolised, sciatic nerve of a calf. He has also tied the carotids of a horse and of a greyhound, employing a liga-

ture of the same kind. It was found, upon subsequent dissection, that the artery was completely occluded, but that its continuity was unbroken, there being simply a depressed ring, scarcely appreciable, at the point where the ligature had constricted it. The autopsy upon the horse and the dog was made in the fifth week, and the nerve ligature was found in each case completely absorbed. Nerve-tissue, Dr. Wyeth says, seems to be especially suitable as a ligature. It is easily obtained, is very strong by virtue of its neurilemma, and is soft and cushioned, since its cylinders of neurilemma are filled with the white substance of Schwann.

An Epigrammatic Criticism.

THE *Philadelphia Reporter*, reviewing a book of Dr. Beard's in its last issue, says:—"The volume will add nothing to Dr. Beard's reputation as a scientist, and we may add that it will not detract anything from it either."

The Chemical Cause of Life.

UP to within a very few years, physiology did not suspect that there was any chemical difference between dead and living protoplasm. Many still will say there is none. But recent researches, beginning by an article of Pflüger's in 1875, point strongly in an opposite direction. One of the ablest essays in the affirmative was written last year, by Dr. Oscar Loew, and Dr. Bokorny, and published at Munich. The result of their investigation goes to show that living protoplasm owes its property of life to the presence of aldehyde groups, which are characterised by intensely active atomic movement. When death takes place, it is coeval with and caused by a transformation of these aldehyde groups into amyde groups, with diminished molecular motion, thus leading to cessation of action.

An Easy Method of detecting the Tubercle Bacillus in Sputum.

PROFESSOR P. BAUMGARTEN, of Königsberg, publishes in the *Cbl. f. d. Med. Wissensch.* the details of a method of discovering the tubercle bacillus which he considers simple and handy. It consists in a combination of the potash method proposed by himself with that of Koch and Ehrlich. Dry preparations of phthisical sputa are made and moistened with a very feeble potash wash (1-2 drops of a 33 per cent. potash solution on a small watch-glass of distilled water). The bacilli can then be plainly seen with a power of 4-500. The bacilli can then be separated from their surroundings by gentle pressure on the cover glass. In order to exclude the possibility of some other bacillus of similar form being mistaken for the tubercle bacillus, the cover glass is now removed, and kept off long enough to allow the moisture adhering to its under-surface to dry, which takes place in a few moments; the cover glass is then passed two or three times through a gas-flame, after which a drop of diluted ordinary aniline colour solution, not too clear (or some other nucleus colouring aniline solution—a watery extract from the ordinary aniline, ink paper will do very well), is dropped on. Under the microscope all the decomposition bacteria now appear an intense blue, or brown, according to the colour-tone of the added colouring solution, whilst the tubercle bacilli remain absolutely

colourless, and are as plainly to be seen as at first. The whole procedure does not occupy more than ten minutes, so that it seems well adapted for practice.

The Poor-Law Superannuation (Ireland) Bill.

THE Select Committee of the House of Commons for consideration of this Bill sat on Thursday and Friday last. Present—Mr. Herbert Gladstone (in the chair), the Solicitor-General for Ireland, Mr. Gibson, Mr. Meldon, Mr. Biggar, Mr. Healy, Sir Patrick O'Brien, Mr. Daly, Mr. Justin McCarthy, Captain Aylmer, Mr. Callan, and other members. The first day was devoted to taking evidence from Mr. Robinson, Vice-President of the Local Government Board for Ireland. On the second day Dr. Jacob was examined at great length, as representing the Irish Medical Association and the Medical Union Officers more especially. On its being known that Parliament would be prorogued at the end of the present week, it became obvious that the Bill could not possibly pass this session, especially as there were a number of witnesses remaining to be examined. It was, therefore, determined to report the evidence to the House, with the intention that the Bill shall be re-introduced early next session.

We are gratified to be able to state that the Government has accepted in all essential points the amendment to the Bill suggested by the Irish Medical Association and the Union Officers' Association, so that, if the Bill passes, it will pass in a form quite satisfactory to the Union officers, medical and non-medical.

Mr. Cope, clerk of the Rathdown Union, Mr. Atkinson, clerk of the North Dublin Union, Dr. Callaghan, of Cork, Dr. Moore, of Ardee, were prepared to give testimony in favour of the Bill; while Mr. Deasy, P.L.G., Cork, and Mr. Stewart, P.L.G., Cavan, were present to give evidence against it. The only one of these witnesses who was examined was Mr. Stewart, who naively informed the Committee that it is the opinion of the Cavan guardians that under no conceivable circumstances should an officer be granted a pension; that if an officer become incapable by old age or illness, he should be removed peremptorily from office, and left to starve if he could do no better; but that he should not be pensioned, no matter how long or how well he had served the Union. This confession of faith, as may be supposed, caused some sensation, and went far to satisfy the Committee that guardians of Mr. Stewart's type are utterly unfit to deal with any respectable employé.

THE Seventh Congress of Russian Naturalists and Physicians is to be held in Odessa from the 18th to the 28th of this month (August).

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby 10; Halifax, Brighton, 13; Bristol, 14; Cardiff 15; Plymouth, Norwich 17; Bolton, Birmingham, London, Edinburgh, Wolverhampton, Oldham 18; Salford, Bradford, Portsmouth 19; Birkenhead, 21; Dublin, Sheffield, Leeds 22; Nottingham 23; Hull, Glasgow, Newcastle-on-Tyne, Blackburn, Preston 24; Sunderland, Huddersfield, Liverpool 25; Leicester 26; Manchester 30.

AMONGST the enormous quantities of stores sent to Egypt one firm alone (Kopf's Extract of Meat and Compressed Food Co.) sent no less than one hundred and fifty thousand tins of Erbswurst soup to the order of Her Majesty's Government for the use of the British troops.

THE Bradshawe Lecture, which was delivered last year for the first time, at the Royal College of Physicians of London, will be delivered this year at the same institution on Friday next, at 4 o'clock. Dr. Long Fox will be the lecturer, his subject being "The Influence of the Sympathetic System on Disease."

"Ferienkurse," or vacation courses of study, are to be held this year as usual in Germany—in Berlin and Munich. The sessions commence on September 20th, and last till the end of October. Classes will be formed in twelve subjects, with a staff of three or four teachers to each subject. The subject of "Medicine and Methods of Examination" has no less than eight teachers—Drs. A. Fränkel, B. Fränkel, Litten, Guttman, Lazarus, Riess, Tubold, and Zuelz.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 21, Madras 31; Paris 21; Geneva 22; Brussels 22; Amsterdam 18; Rotterdam 15, The Hague 16; Copenhagen 26; Stockholm 26; Christiania 23; St. Petersburg 51; Berlin 35; Hamburg 26; Dresden 30, Breslau 43, Munich 32, Vienna 25, Prague 29, Trieste 29, Rome 25, Naples 30, Turin 24, Venice 34, Philadelphia 24, and Baltimore 32.

CONTRARY to what is usual at this season of the year the death-rate from diarrhoea in the large towns last week showed but a very slight increase upon that recorded in recent weeks, there being but one town wherein it was excessive, namely, in Leicester, the death-rate reaching 10.3 of the population. The highest annual rates from measles were 1.9 in Huddersfield and 2.0 in Hull; from scarlet fever, 1.3 in Sunderland and 2.5 in Derby; and from "fever," 1.1 in Preston, 1.9 in Derby, and 2.0 in Hull. Small-pox caused but one death in London and its outer ring of suburban districts, 3 in Newcastle-upon-Tyne, and one in Hull, 5 deaths being the sum total registered in the whole of the United Kingdom from this cause.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE TEACHING OF NATURAL HISTORY IN EDINBURGH.—We learn that matters are not improving with regard to Professor Ewart, and that all his class assistants have resigned, as they find that they are unable to work comfortably with him. Something will have to be done before the winter session begins, and the Senatus will have all their work to do to restore order.

ROYAL COLLEGE OF SURGEONS AND PHYSICIANS, EDINBURGH.—Out of seventy candidates who presented themselves for the recent final examination for the double qualification

of this College, twenty-eight failed to satisfy the examiners. The examinations appear to have been conducted with great fairness, and there are evident signs of an attempt to raise the standard.

THE HEALTH OF EDINBURGH—INFECTIOUS DISEASES.—At a meeting of the Public Health Committee on Thursday week, several outbreaks of infectious diseases were reported by the Medical Officer of Health. These, it was stated, had been properly isolated, and it was believed that the progress of the disease had been stopped. One of these cases had occurred in a dairy in the west end, and the others were connected with the outbreak of typhus in Fountainbridge which was reported at last meeting of the Committee. Since that time five additional cases had occurred—the source of infection being the same. Eleven cases were now under treatment in the Canongate Hospital, and were all progressing favourably. The statistics of the fever wards in the Old Infirmary were also handed in. From these it appeared that there were 17 cases of typhoid under treatment, 19 cases of scarlet fever, and 6 cases of erysipelas—in all 42. There were 32 empty beds—74 being the number of beds for fever cases which the managers of the Infirmary agreed to maintain for infectious diseases from the city. At the same meeting several cases of insanitary houses were reported, and summary action was ordered to be taken, inasmuch as from damp and other causes the houses in question were shown to be quite unfitted for human habitation.

HEALTH OF EDINBURGH.—The Edinburgh mortality for the week ending with Saturday, the 5th inst., was 80, and the death-rate 18 per 1,000. At least 40 deaths were due to diseases of the chest, and 7 to zymotic causes, of which 3 were from fever, 1 from scarlatina, and 3 from measles, the intimations of these diseases being respectively 6, 39, and 6.

THE WAR IN EGYPT.—Dr. A. G. Kay, of the Army Medical Department, who has been for some time in charge of this branch of the service at Leith Fort, left for London on the 10th inst., in response to orders from head-quarters, to join the *Prussian* transport ship, which sailed for Egypt on the 11th inst.

VITAL STATISTICS.—From the Registrar-General's returns for the week ending Saturday, August 5th, we learn that the death-rate in the eight principal towns of Scotland was 21·3 per 1,000 of estimated population. This rate is 0·2 above that for the corresponding week of last year, and the same as that for the previous week of the present year. The lowest mortality was recorded in Aberdeen—viz., 15·5 per 1,000, and the highest in Paisley—viz., 28·5 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4·8 per 1,000, or slightly above the rate for the previous week. Bowel complaints were the most prevalent of the epidemic diseases. Six deaths from measles were registered in Leith. Acute diseases of the chest caused 74 deaths, or 8 less than the number registered during the previous week.

UNIVERSITY OF EDINBURGH.—**NEW SCHOLARSHIP IN MIDWIFERY.**—At the last meeting of the Senatus of the University of Edinburgh, a letter was read intimating the foundation, by Mrs. Thomson, of Rosalia, Hawick, of a scholarship, to be called the James Scott Scholarship, in memory of her father, the late James Scott, of Allanshaws. This is the second scholarship in the same department that is open to the students of the Edinburgh University, Mrs. Buchanan, of 49 Moray Place, having two years ago provided the funds for a scholarship in gynecology. In both cases the scholars receive the yearly interest of £1,000.

GLASGOW ROYAL INFIRMARY.—The quarterly meeting of the managers of the Glasgow Royal Infirmary was held on the 7th inst., when Mr. W. M'Ewen, the chairman, presided. The following new appointments were made:—Dr. J. Dougall and Dr. J. W. Anderson, dispensary physicians; Dr. D. C. Black and Dr. W. G. Brock, extra dispensary physicians; and Dr. W. G. Shaw, extra dispensary surgeon.

DEATH-RATE OF GLASGOW.—During the week ending with Saturday, the 5th inst., the death-rate of Glasgow was 24 per 1,000 of the population. For the corresponding weeks of 1881, 1880, and 1879 it was 24, 25, and 18 respectively.

UNIVERSITY OF ST. ANDREWS.—We understand that the Chair of Natural History in the University of St. Andrews, vacant by the appointment of Dr. Alleyne Nicholson to that of Aberdeen, has been presented by the patron, the Marquis of Ailsa, to Dr. Mackintosh, at present Superintendent of the Murthly Asylum. Dr. Mackintosh has acted for some time as Extra-Examiner to the University of Edinburgh. We trust that the present appointment is only a stepping-stone to Dr. Mackintosh's recognition as one of our leading naturalists.

Literature.

CARPENTER'S PHYSIOLOGY. (a)

ALTHOUGH Dr. Carpenter's well-known "Principles of Human Physiology" has for some time ceased to hold the place it so long retained as the only considerable English treatise on the subject, it still continues to be one of the most popular scientific books, as is evidenced by the rapidity with which edition after edition is exhausted. Of late years the competition of Dr. Michael Foster's admirable "Text-book" has in a considerable measure deposed the "Principles" from its place in the library of medical students; but the more ambitious even of these still find it expedient to fortify themselves with a knowledge of Carpenter ere presenting themselves as candidates at the more important University examinations. It may perhaps be urged, without any improper construction being placed on the assertion, that the arrangement of the "Principles" is its worst feature, and that many who now turn from its pages in weariness and despair would remain faithful to it if the vast stores it contained were presented in a somewhat different manner. The accomplished editor of the book is doubtless best able to judge of the expediency of adopting any change of form in the work with which he has so long been associated under its present shape; but it cannot be denied that since its first appearance it has been gradually but surely regarded as a member of the "heavy" series, and that now, in comparison with other and equally solid treatises, it is not modified to meet the changing needs of the hour.

Whatever may be said of the arrangement of the work, however, nothing can detract from the value of its contents or the ability with which these are brought in each successive edition to be abreast of science at the date of issue. So rapid, nevertheless, is the growth of physiology, so unstable is it in many branches, that it is impossible to write a work one month which shall exactly reflect the knowledge of the next; and for many years to come it is likely that the same remark will hold good.

In the present edition less prominence has been given to the subject of pathology than in the former impressions; and in view of the excellent special works now accessible to students of this branch of medicine, there is less need for incorporating it in a volume specially devoted to physiology. In pure physiology, however, there has been ample scope for amending, and improving, and recasting work, and this has been done in the most admirable manner.

In the section on digestion a careful review of the chemistry of pancreatic secretion is offered, the existence of three ferments being insisted on; and the question of the bile-functions is dwelt upon at considerable length. The history of blood contained in "Carpenter's Physiology" has always been one of the most interesting chapters in the book, and it still retains its value in this respect, although it perhaps, as much as any portion of the treatise, will demand considerable alterations in the next succeeding edition in view of the most recent discoveries in connection with the physiology of the blood.

The physiology of the nervous system occupies a goodly portion of the whole work, and is particularly complete in the details it offers concerning the functions of the various constituent organs, those of the spinal cord being explained in a way that is fully as satisfactory as is possible in the present state of knowledge. "The Influence of the Nervous System on the Organic Functions" is the title of a singularly suggestive chapter, in which the theory of trophic nerves is elucidated, with copious references that lend it an especial value. As a *résumé* of what is known on the point it must be most serviceable, while it necessarily cannot be appealed to in settlement of this fruitful subject of discussion.

The chapter on development has been expanded and revised by Mr. D'Arcy Power; it is a most faithful epitome of later embryological researches, and a useful source of information concerning them.

(a) "Carpenter's Principles of Human Physiology." By Henry Power, M.B. Ninth Edition. London: J. & A. Churchill.

The presence of a complete and well-arranged index is a feature of this edition, which serves to render reference at once easy and satisfactory, and adds much to the facility of study, which, in so extensive a volume, is of no small importance.

Speaking generally, it must be said that the ninth edition of "Carpenter's Principles of Human Physiology" in no way falls short of the peculiar excellencies which have made this work to rank among the classical hand-books of English science.

Correspondence.

THE ETHICS OF COMPULSORY VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Medical Press* of the 12th of July I showed that the elaborate argument of Mr. Collins against compulsory vaccination contained in the issue of the previous week was entirely fallacious. Mr. Collins, replying to my letter, does not attempt to substantiate his argument, but kindly informs me that, though a less eminent moralist than Mr. Herbert Spencer, I am free to think that the law rightly limits the rights of citizens for their own personal interest, and then proceeds to accuse me—first, of making a suicidal statement; and, secondly, of misquoting his words.

Though Mr. Herbert Spencer may be of opinion that a man's personal rights should not be interfered with as long as they do not trespass directly on the rights of others, surely he would not maintain that parental rights should be governed by the same principle. If this were the case, a man would have absolute control over his children for life and death. What would then become of morality and education? And yet Mr. Collins appears to consider that this principle is the "foundation of our social relations."

"If vaccination were not compulsory, the unvaccinated minority would probably be much larger, and might even become a majority." Mr. Collins considers this statement suicidal. I can only regret that the ignorance, carelessness, and prejudice of parents among the masses of the population are greater than Mr. Collins is aware of—so great, indeed, as to afford full justification for the statement. If the mothers of our lower orders were as well acquainted with the results and benefits of vaccination as Mr. Collins is, there would be less need to "whip them up" by means of the vaccination officer.

If Mr. Collins will read my first letter more carefully, he will find that I neither quoted nor misquoted him, but deduced from his letter the opinion that "the Public Health Act is a sufficient protection against any one who suffers from small-pox communicating the disease to others." And, apparently, I was quite right in attributing that opinion to him. Let me recommend Mr. Collins to peruse at his leisure a letter by Dr. Higham Hill, late special Government medical officer in New South Wales, which appeared in the *Lancet* of July 29th. Dr. Hill—who investigated an outbreak of small-pox in New South Wales, where vaccination is not compulsory, and isolation was adopted—has probably had more experience of small-pox and the means of preventing it than even Mr. Collins. He sums up his interesting letter with the following remarks:—"Isolation by the quarantine system is, doubtless, a valuable sanitary measure in outbreaks of small-pox occurring in towns like Leicester and Sydney, where vaccination has been greatly neglected; but it is very harsh and severe in application, impracticable in many cases, and most expensive. It can at best only rank as an assistant to that great prophylactic, vaccination, in the stamping out of small-pox; and it is trusting to a broken reed to rely upon it as at all a substitute for efficient vaccination of communities."

To conclude, I hold that vaccination should be compulsory, for the following reasons:—

1. As a safeguard for each child against itself suffering from the evil effects of small-pox.
2. As rendering each less likely to contract small-pox, and so infect others.
3. Because efficient vaccination is the only way of stamping out small-pox.

Apologizing for the length of this letter, which I intend to be the last on my side,

I remain, yours faithfully,

SIDNEY DAVIES, B.A. (Oxon), M.R.C.S.

Tottenham, Aug. 4th.

[This correspondence must now close.—Ed. M. P. & C.]

DUDGEON'S SPHYGMOGRAPH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Black is quite correct in saying that the tracing varies with the amount of pressure applied to the instrument by means of the strap; but this is the case with all sphygmographs that are attached to the wrist by a strap. He is wrong, however, in supposing that the pressure of the strap in my instrument influences the pressure of the spring on the artery. The strap must be drawn more or less tightly, according to the position of the artery, whether it be deeply imbedded in the tissues or more superficially placed, and according to the force of the heart's action, the degree of fullness of the artery, and the stiffness or elasticity of the arterial walls. But the rule for taking a tracing is to adjust strap-pressure and spring-pressure so that the needle is seen to play over the centre of the paper with the greatest freedom—that is to say, makes the highest up-stroke before setting the clock-work in motion; and this, with a little practice, can be easily done in a few seconds. The strap is drawn to the degree of tightness that will bring the stud of the spring down upon the artery. The regulator of the spring shows in ounces and quarter-ounces the weight the artery moves at each pulsation; in other words, the pressure exerted by the spring on the artery. The strap does not alter the pressure of the spring, but only the pressure of the solid flanges of the instrument on either side of the artery. If the strap be not drawn tight enough, the needle will not come on the paper; if drawn too tight, the needle will be pushed beyond the paper. On the other hand, if the pressure of the spring be insufficient, the needle goes beyond the paper; if excessive, it does not get on to the paper. I have fully explained the mechanism of the instrument in the little book you reviewed, to which I would refer all who have any doubts as to the correctness of the mechanical principles on which my sphygmograph is constructed.

I take this opportunity to mention that some imitations of my sphygmograph have been imported into this country from the Continent, which, though resembling the original instrument very closely in external appearance, are altogether wanting in accuracy. Some of them will not act at all; others are not regulated, as mine is, to magnify the pulsations fifty times, but magnify them either more or less than that; and they do not propel the smoked paper through the machine in ten seconds, as mine does, but at very various rates. I do not think many of these instruments have been sold in this country, but I may repeat the caution I gave in my book before I knew that imperfect imitations of my sphygmograph had been manufactured—viz., that purchasers should endeavour to see that their instrument-makers supply them with sphygmographs made by the only competent maker—Mr. John Ganter. It seems to be a custom of the trade that the instruments they sell, by whomsoever made, shall only bear the name of the seller; but, in the case of an instrument like this, which requires such extreme care and delicacy in making all the required adjustments, it strikes me that it would be a great advantage to have a guarantee that the instrument was really made by one who thoroughly understands all the requirements of the instrument, and is able to carry them out. I have no pecuniary interest in the sale of the instrument, but I am very much concerned that those which are sold should be in all respects as perfect as that I use myself and have described in my book; and, therefore, I give the above caution, which is all the more necessary, as spurious and incorrect instruments are now in the market, which, if they fall into the hands of practitioners, may bring my sphygmograph into unmerited discredit.

I am, yours, &c.,

53 Montagu Square, London,
9th August, 1882.

R. E. DUDGEON.

University of London.—The following is a list of candidates who have passed the entire Intermediate Examination in Medicine:—

First Division.	
Anderson, George Elliott Caldwell	Jones, Samuel Cromwell
Bowes, William Henry	McCabe, William Alex. Bowes
Brock, James Harry Ernest	Purlow, Charles Edwin
Carr, John Walter	Spong, Charles Stuart, B.Sc.
Elliott, John, B.Sc.	Watson, William Ivens Buswell
Hayman, William Speed	Wells, George Lee
Innes, Charles Barclay	Woolbert, Henry Robert.
Jones, Frederick William Caton	

Second Division.

A'le, Joseph Rosamond
Andrews, Charles
Arkie, Charles Joseph
Barnett, Lawrence
Barnard, Letitia Caroline
Braden, Richard William
Caldecott, Charles
Chapman, Harry Cecil
Cocking, William Tusting
Cooper, Henry Charles Evans
Dutt, Upendra Krishna, B.Sc.
Fenton, Herbert Alfred Hill
Fisher, Henry Holdrich
Flamming, Percy
Frame, Alfred Cromwell
Francis, Alfred George
Hinds, Frank
Hodson, Gerald George
Hurst, Walter
Irvin, Frederic David
Jobbins, William

Lankester, Herbert Henry
Little, Arthur Nicholas
Mumby, Langton Philip
Penrose, Francis George
Pettifer, Edmund Clever
Pilgrim, Herbert Wilson
Randell, Reginald Maurice H.
Robinson, Henry Betham
Rouse, Rollard Edward
Sellick, James Henderson
Strugn-H, Walter Thomas
Swain, James
Taylor, Alfred Ernest
Trautman, Frank
Turner, Philip Dymock
Vernon, John James D. an
Vinos, John Foster
Voelcker, Arthur Francis
Whitcombe, Philip Percival
Williamson, Richard Thomas.

Same examination, but excluding Physiology :—

First Division.

Carpenter, George Alfred.

Second Division.

Freeland, Freeland John

Lankester, Alfred Owen.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners held on Monday, the 24th of July, and following days, the under named gentlemen having passed their Final Examinations for the Letters Testimonial and having made the declaration and signed the Roll, were admitted Licentiates, viz. :—

Bolger, James Tandy
Coall, Robert Henry
Cooper, Austin Nathaniel
De-lamery, Percy Herbert
Dillon, Bernard Joseph
Dutch, Myer Akiba
Garland, John Peter
Greene, Arthur Joseph
Hayes, Alfred Adolphus
Hoey, John Colclough
Howard, Timothy
Lane, James
Lalor, Joseph
McDonagh, John Michael
McGee, William

McGuire, James
McNaught, Frederick Joseph
Mullan, Edward Duddy
Newell, Percy
Nolan, Michael Joseph
O'Connell, Thomas
O'Connor, William Edmond
Pollock, Rowland
Power, John Turner
Roe, Francis Christian
Sunders, Robert Corles
Sweeney, Michael Patrick
Thompson, Wm. Christopher
Todd, John Joseph
Wynne, Edward

Notices to Correspondents.

SENILE.—It is highly unlikely that you are correct in your surmise. In a young person there are many causes which might act to bring about the condition, and you ought to make careful inquiries for the sake of satisfying yourself that the enlargement is not due to the action of some very common, even though unpleasant, influence.

G. K.—The sulpho-carbolate ; it has been occasionally employed in this country for the cure of hemorrhoids, and with considerable success. There must be no delay in the treatment you have commenced, and it would be well even to hasten healing now as much as possible.

PUBLIC VACCINATOR (Sldmouth).—Yes, the grant was passed last week in Committee of Supply.

DR. CASSIDY (Indiana) will please receive our thanks for his complimentary note.

DR. PEARSE (Plymouth), HOMO (Northumberland).—Letters unavoidably held over.

DR. E.—It would not be in accordance with our rule to let you see it before it appears in the columns of the *Press*. But we can, perhaps, serve your purpose by putting you into communication with the writer, with whom it will then rest to accede to, or decline, your proposal.

CURIOUS.—You probably mean the description of Humphrey, Duke of Gloucester's corpse. It occurs in Act III., scene 2, of the second part of King Henry VI., and is spoken by Warwick. The passage—

"His hands abroad displayed, as one that grasped

And tugged for life and was by strength subdued"

has been the subject of comment on more than one occasion ; but like all Shakespeare's descriptions, it is singularly correct, and the whole picture of the murdered man is descriptive of asphyxia.

MR. CHANDLER.—You have chosen the best for your purpose. It is published by Baillière and Co., and costs two guineas.

MR. G. HOWARD.—Yours is not a case for medical treatment ; the remedy is in your own hands : take plenty of outdoor exercise, indulge freely in cold ablutions, and, above all, avoid quacks.

MR. HAZLITT.—The phenomenon you mention has been noticed many times before. It is a consequence of the summer season and blue-bottle flies in conjunction. It has no probable relation with the production or multiplication of bacilli.

MR. S. R. RICHARDS.—The examinations are now finished, and will not be resumed until November.

DR. W. T. BLACK.—The report is interesting, and shall appear in our next.

PROFESSOR ESMARCH ON AMERICAN SURGERY.—Esmarch has just published a lecture which he delivered some months ago before the

Physiological Society of Kiel on the treatment of President Garfield's wound. The wound, he maintains, was not mortal, and the injury to the vertebra could have been healed. The death of the patient was mainly due to the loose way in which the antiseptic treatment was applied. A great mistake, too, was made in searching for the bullet. Had the American surgeons imitated Von Langenbeck's example, who did not attempt to extract any of the pellets when the German Emperor was wounded, and had the antiseptic treatment been rigorously applied, the President might, the Professor maintains, be alive now.

DR. WILSON.—Thanks for compliments. We fancy unqualified assistants will shortly be having a bad time of it. It really now depends on the profession whether they will get rid for ever of this evil.

M. N. O. (Manchester).—The Coroner for Manchester is anxious that more inquests should be held. Other coroners try to limit the number. We have several times commented upon the subject and would do so again were there anything new in the case you mention.

DR. W. F. (London).—We shall try and publish list of all prizes open to English writers. This will take some trouble. The "Ebert" prize is open to you—£800. Subject : "Embryological Researches." We shall write to Secretary of Academy.

MR. SMITH.—Our position is unassailable. We have always opposed the Registration Clause as applied to medical men. The policy of the paper referred to is notoriously opposed to that of the body of general practitioners.

DR. E. BROWN.—Sorry we cannot help you in the matter.

SPHYGMOGRAPH.—Dr. Dudgeon's book is the one you want. The new sphygmograph will in a short time become as necessary to the practitioner as the thermometer or stethoscope.

SFA.—Correspondent's letter held over owing to pressure on space.

REGISTER.—Out-door Poor-law Medical Relief is a very good subject. We shall consider it, and publish probably a series of articles upon it. POOR-LAW MEDICAL OFFICER.—"£12 a year, finding all drugs, attending over so many thousand acres." We cannot pity you. You have taken the appointment—for what reason ? Throw it up.

Vacancies.

Downpatrick Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to the Resident Medical Superintendent by Sept. 1st. (See Advt.)

Appointments.

BERNARD, A. G. F., M.R.C.S., Medical Officer to the Troops at the Seaforth Battery.

CANE, F. E., L.R.C.S. Ed., L.R.C.P. Ed., Resident Dispensary Surgeon to the Bradford Infirmary and Dispensary.

CRESSWELL, N. E., M.D., M.R.C.S., Medical Officer of Health for the Towcester Rural Sanitary District.

JONES, R., M.R.C.S., Medical Officer of Health for the Flint Urban Sanitary District.

LILLEY, G. H., M.D., M.R.C.P.E., Medical Officer to H.M. Convict Prison, Portland.

MURIEL, C., L.R.C.P. Lond., M.R.C.S., Resident Medical Officer to the Guest Hospital.

ORB, H., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Filey District of the Scarborough Union.

PERCIVAL, G. H., M.B. Lond., M.R.C.S., Medical Officer of Health for the Northampton Rural Sanitary District.

SPENCE, W. J., L.R.C.P., L.R.C.S., House Physician to the Bradford Infirmary.

STEELE-PERKINS, G., M.B., C.M. Ed., M.R.C.S., L.R.C.P. Lond., Medical Officer to the Port of Exeter.

Births.

KNIGHT.—August 9th, at Palmryra, Whitechurch, co. Dublin, the wife of Charles F. Knight, M.D., of twin sons.

RICE.—August 8th, at the Infirmary, Plumstead, the wife of G. Rice, M.B., C.M., of a daughter.

Marriages.

DOCKRELL—OLDFIELD.—August 9th, at St. Jude's, Kilmalsham, Morgan Dockrell, M.B., B.Ch. of Monkstown, co. Dublin, to Emily, only daughter of the late Alexander Oldfield, of Nottingham.

EDWARDS—MORRIS.—August 10th, at Spalding, Lincolnshire, Edward A. Edwards, of Hortham, to Alice Maud Mary, daughter of Edwin Morris, M.D., F.R.C.S., Spalding.

MASON—SHINE.—August 8th, at St. Peter's Church, Dublin, Samuel R. Mason, A.B. and M.B., F.R.C.S.I., of Dublin, to Mary Elizabeth Shine, daughter of Jer. Shine, Esq., Ballymacreese, co. Limerick.

TRIMBLE—ORAM.—August 9th, at the Parish Church, Bury, Charles J. Trimble, L.R.C.P., L.R.C.S.I., of Bamber Bridge, to Beattie, daughter of the late Robert Oram, Esq., of Bury.

Deaths.

GELL.—August 9th, suddenly, at his residence, Southam, near Rugby, Alfred Scott Gell, M.R.C.S., aged 48.

GILES.—August 8th, at his residence, Torquay, Richard Giles, M.D., late of Oxford.

KINANE.—August 11th, suddenly, at Templemore, Michael Kinane, M.D.

MILLER.—August 7th, James Miller, M.D., of Aberdeen House, Great Percy Street, W.C.

MOGG.—July 28th, at Great Smeaton, Joseph William Oliver Mogg, L.R.C.P. Ed., L.R.C.S. Ed.

WHITE.—August 11th, at his residence, Borris Castle, Queen's County, Dr. William White, aged 73.

A Course of Lectures

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE VI.

MR. PRESIDENT AND GENTLEMEN,—There is yet one other skin disease of such extreme interest in varied directions in reference to questions of diathesis, that I feel obliged to bring it in some detail before you—I refer to lupus; and I comprise under that name not alone the common form, but certain other more or less rare varieties of the process which I trust to be able to claim as certainly belonging to the lupus family. I am not about to trouble you with any detailed description of those several forms, but in order that the questions as to cause, relationship, and the diathesis behind them should come clearly out, it is necessary that I should recapitulate a few facts.

Concerning common lupus, then, I would assert that it is well known that it begins as a cell growth in the corium, that it always begins as a single patch, and always spreads at its edge by the infection of the adjacent skin, and that it very usually tends in the end to become multiple. Its multiplicity as well as its local spread is due to its infective power, and its secondary growths are almost always placed in close proximity with the parent one. It never in any case, however extensively multiple its patches may be, shows any tendency to symmetry; in all these features its clinical history resembles that of a local cancer. That which is true of the locally restricted

form of epithelioma known as "rodent ulcer" is true also of common lupus. Both are slowly progressing new growths which after a time inflame and ulcerate and then cicatrize. Both are curable by free measures of local extirpation and by those only. You cannot influence either except in the most minor degree by any remedies which appeal to the general health. Neither shows any power of producing gland disease, nor any tendency to spontaneous amelioration. The one is a disease chiefly, however, of early life, and the other of adult age. The varieties which common lupus presents do not offer us anything very exceptional to what I have said. According to the constitution of the individual, the state of health, the kind of diet, and the climate, lupus may influence and ulcerate much or little, and in connection with these almost accidental differences, the old, and I trust now abandoned terms exedens and non-exedens came into use. It may vary also very much as regards its restriction to a single original patch, or its tendency to multiplicity. Sometimes we see a single patch steadily spreading at its edge through the greater part of a long life, and never showing any tendency to produce new ones. This probably depends upon comparative vigour of constitution and a lesser degree of susceptibility. The explanation of the secondary patches when they occur is in all probability that they are the result of infection. As already stated, the multiplicity is never spontaneous. It is not, I think, beside the mark that I should ask attention to the methods of cure which have been proposed for lupus as indications of some slight affinity with the diathesis of malignant diseases. We have lately been taught by Professor Volkman that every portion of the diseased tissue should be most carefully eradicated by the spoon. But his proposal had nothing whatever in it that was original in its theory, for long previously we had all been accustomed to act on the same principle and to seek by the knife, the caustic, or the cautery to utterly eradicate every fragment of the new growth. If I am not mistaken, we owe to Mr. John Gay, to whom surgery is indebted for many other practical suggestions—the radical proposal that the lupus patch should be cut out with the knife. It is essential that whatever method be adopted it be pur-

sued unflinchingly and over and over again if needed. In this way lupus may be cured, and it is not too much to hope that now this principle is becoming widely understood, and the profession is becoming bold in its practice, we shall before long witness a great diminution in the number of those who are disfigured by it. My object, however, in mentioning the success of vigorous local measures is not to enforce a lesson in therapeutics, but to intensify our conception of common lupus as a local new growth possessing infective properties. I might add that it often begins from some slight local injury, a sting, an abrasion, an acne pustule. Amongst the interesting varieties which common lupus presents we have a rare form, which we may suitably call "acne-lupus," which occurs in scattered spots over the face, these spots being evidently connected with sebaceous follicles, and often with previously-existing acne pustules. Their arrangement, however, I believe, never follows that of acne in being symmetrical, but always obeys the law of lupus, in that the secondary tubercles are more or less near to the parent one. In another variety lupus attacks mucous membranes and produces slowly spreading ulceration, attended with papillary outgrowth. That lupus of mucous membranes as we see it affecting the conjunctiva, the gums, the palate, &c., is really lupus is proved by its very frequent association with well characterised disease in the skin. In another extremely rare variety, of which I have seen but one example, the lupus growth is exceedingly trivial, does not ulcerate at all, spreads rapidly at the edge, leaving behind it a thin, supple, and healthy scar. In yet another variety it receives modification probably from the part in which it occurs. It is but seldom that we see well-characterised lupus on the hands or feet. But we often encounter a form of disease which takes its place in which there is less evidence of new growth and more of inflammation and tendency to papillary hypertrophy. To this, the form of inflammation due to dissection wounds on the hands, necrogenic warts of Dr. Wilkes, necrogenic lupus, I think, belongs. There is yet another variety in which the surface of the lupus patch does not ulcerate, and is not raised, but weeps, like an eczema, presenting a condition which would at first sight, and certainly by the inexperienced, be mistaken for eczema. The points to which we appeal in proof that all these very different-looking inflammations of the skin are really lupus are that they all take origin at a single spot, spread slowly but constantly at their edges, and whether they ulcerate superficially or not, always have a cicatrix where they have passed. I do not think that there would be much hesitation in accepting the statement that a disease which presents these features and is not either a cancer or syphilis must be a lupus.

We have arrived, then, at the end of our first stage in the inquiry, and have seen that this peculiar form of new growth in the skin and mucous membranes to which young people are liable may, while observing identities in essentials, manifest very peculiar differences in external appearance. It may be single patches or multiple, it may look like itself or an acne, a lichen marginatum, or an eczema. These differences have more to do with the original differences in the texture of the skin which is attacked than any other class of causes. Let us notice the peculiar thinness and delicacy of the skin in the boy who furnishes us the example of what I have called lupus marginatus, in which exceedingly little growth and no ulceration occurred. We have now to take another step and to encounter another process with far more important differences. The diseases which are known as lupus erythematosus, and its variety lupus sebaceus are more than a mere modification of common lupus. They are distinct varieties, or, if one dared to use such a word, they are almost species. They manifest relationships with other type-forms of skin disease almost as close as those they bear to common lupus. Had it not been for the fact that the common form and erythematous form often exist together or slide into each other by insensible relations, we might have been tempted to prefer to call erythematous

lupus by some other name. Its most important difference of feature is that it usually occurs symmetrically. Thus there is far more reason to believe that it is due to a constitutional peculiarity than is the case with the absolutely non-symmetrical and local lupus. The arrangement of the bat's body and wings on the nose and cheeks in erythematous lupus is well known. The parts affected next to the nose and cheeks are almost always the ears, and next to them the backs of the hands. In this spreading there is no continuous connection between the patches. They are separate from each other, and apparently independent. The evidence as to multiplication by infection is far less strong than it is in the common form. Though there can be not the slightest doubt that this kind of advance does take place at the edges of the patches, and remembering what I had to advance in our last lecture in reference to the possibility that all inflammatory processes may be capable of infecting the blood, I am unwilling to admit, even when we see lupus erythematous on the backs of both hands, whilst the whole of the rest of the upper extremities and trunk remain free, that we have conclusive proof that these secondary manifestations are independent of the original patches on the face. The symmetry cannot possibly be due to any other cause than pre-existing proclivity of tissues; but it is just possible that it is not independent of an infective process also. At any rate, it is true that this disease is wonderfully symmetrical; the ears, the cheeks, and the backs of the hands show exactly the same conditions on the two sides. The variety to which the name sebaceous is given is often not erythematous at all. There may be no redness and no swelling, but the skin becomes dry, rough, and shrunken, and the orifices of the sebaceous follicles are very conspicuous, like the inner side of a nutmeg-grater. This form is also accurately symmetrical, but it rarely leaves the face. If you see it on the nose you may look for it on the ears, and in the middle of the concha of each, just where in acne a group of comedones is often seen there will be a little patch of lupus. Lupus sebaceous and lupus erythematous are frequently mixed in the same case, and they are probably the same disease modified by peculiarities in the skin. Although I have described them both as usually symmetrical, not unfrequent exceptions occur under all conditions. They show their alliance with lupus by leaving the skin which they have affected in a state of scar. I suggested that lupus erythematous had alliance with other skin diseases, and I was thinking especially of psoriasis and those modifications of nutrition known as chilblains, and my suggestion will now be that it owes its peculiarities to the admixture in varying proportions of these two diatheses with that of lupus. As regards chilblains, it is sometimes when the ears and the backs of the hands are affected quite impossible to differentiate between them and lupus erythematous. The latter, like chilblains, is always worse in cold weather, and it usually occurs to persons of feeble circulation, in whom venous congestion easily occurs when the surface is chilled. Its alliance with psoriasis is shown, not alone by its symmetry, but by the fact that in exceptional instances the scaly patches may be seen on the tips of the elbows, with now and then a diffuse psoriasis condition of the whole surface. Children and young persons are but rarely the subjects of lupus erythematous, nor does it usually attack those in whom the skin is thick. Thus, I think we may assert respecting lupus as a whole that it is a sort of cross produced by conjoined tendencies at once to scrofula and cancer, and that it receives many modifications in respect to peculiarities of the patient's skin and his morbid tendencies in one or the other direction. If he has a degree of tendency to the psoriasis diathesis it will assume the erythematous form, and it will be then especially prone to attack the extremities if it encounter also the proclivities to chilblains. I have yet left for consideration another variety of lupus concerning which a few words must be said. It is one which differs much from all forms which we have described, and yet I submit that it is really

a lupus. I know as yet but of four recorded examples of it. The late Dr. Tilbury Fox showed at a meeting of the Pathological Society a young man on whose thigh were two different and very peculiar conditions—one being a congenital port-wine stain and the other a persisting vesicular eruption which had been developed at a later period. As a result of microscopical examination, Dr. Fox believed that the vesicles in question were in connection with the lymphatic trunks and spaces. At the same meeting I mentioned two cases in which I had for a considerable time taken much interest, but which we neither of us then thought to be exactly similar. A third case has subsequently come under my observation, and I have now no hesitation in believing that the four are examples of the same malady, and that the lymphatic spaces and the lymphatic trunks are really implicated. Whether it deserves the name of lupus lymphaticus I must leave to your judgment. All the four patients were boys; in all the disease had existed for several years; in all it was slowly spreading at the edge, and producing, near to the parent patch, secondary ones, which were apparently due to infection. In none of the cases was there ulceration, and in all the eruption consisted of little firm resisting vesicles which showed no tendency to rupture, and were aggregated into confluent groups. Upon these vesicles and at their bases were little tufts of capillaries which were almost fervid in character. By microscopic examination of portions cut from all three cases I have satisfied myself that the lymphatic trunks are dilated, and further, that there is a new cell-growth around them exactly like that of common lupus. So similar is this cell-growth to that of lupus that a very able microscopist who examined one of my slides took it for a specimen of that disease. It is right that I should add that in this microscopic examination I have been much assisted by Mr. Sangster, Mr. Robert Parker, and my eldest son. My belief is that the malady in question bears the same relation to the lymphatics that lupus erythematosus does to the blood-vessels, and that it is an instance of the existence of a new growth assuming clinical features in connection with the peculiarity of the special tissue in which it takes its origin. As in cancer everything depends on the tissue first affected, whether the growth is a melanosis, an epithelioma, or a scirrhus, so in lupus permanent modifications are stamped on the process according as it begins around the sebaceous glands, the blood-vessels, the lymphatics, or in the corium. When the type has been once taken it will be retained. The various forms of iritis are of peculiar value as indications of diathesis. Its occurrence in infancy, a very rare event, is usually indicative of syphilis. In adolescent periods, and early adult life, we have different forms of iritis which generally imply the inheritance of gout. This inheritance is, in such cases, often modified by other individual peculiarities, such as feebleness of circulation and proneness to chilblains. When this is the case, a very peculiar form of multiple arthritis which begins in the last joints of all the digits, and often affects them exclusively, is sometimes seen. The explanation of last joint arthritis is doubtless to be found, as I have just suggested, in the peculiarity of circulation which in later life gives tendency to symmetrical gangrene of the extremities, as so well described by Raymond, and more recently amongst ourselves by Dr. Southey. It is not, however, due to this alone. There is always joined with it an inherited tendency to gout. The cases of recurrent iritis which we meet with so frequently in adult men, but occasionally in women also, in which the attack is sharp and severe, the interval of immunity complete, and the recurrences take place once a year, or oftener, is, I believe, distinctly an indication of rheumatic gout. It does not very often happen to those who suffer severely from declared gout, and it is very rare in connection with rheumatism only. We meet with it in those in whom there is inherited proclivity to gout, who have lived rather freely, who are susceptible alike to weather

and to diet, but who have never themselves had an outbreak of true gouty arthritis. The fact that this form of severely paroxysmal iritis occurs much more frequently in men than in women supports the general statement which I have just made. In women of middle age, or a little past it, we encounter iritis in another form, as an insidious disease, attended by a little conjunctival redness, and some sensation of heat and irritability, and gradually, without any definite paroxysms, producing extensive adhesions. The little exacerbations which attend it are often more definitely influenced by exposure to cold and wind than by diet. This form of iritis is, I believe, almost invariably a consequence of a remote inheritance of gout.

We tried in a former course of lectures to give a definition of the word catarrh which should enable us to employ it for more accurate clinical purposes than it is often used. I suggested that it should be held to imply identity in cause, and not similarity in result. There is surely no good reason why all forms of inflammation of mucous membrane attended by free discharge irrespective of their causes, which are often very different, should be called catarrhal. On the other hand, if we use the word in the sense which I contend for, we shall find it applicable to other inflammations besides those of mucous tissues. In so doing we shall construct a large and perfectly natural group of maladies. Whatever is the result of catching cold is catarrhal; conditions which follow from other and dissimilar causes, however similar their results, ought to be refused that name. The catarrhal diathesis, using the word in this sense, is one of the three fundamental ones. It is not due to any specific or any specialised cause. Every organisation possessing a nervous system must be supposed to be capable of manifesting it, for its essence consists in proneness to inflammatory congestions excited in a reflex manner through the influence of cold applied to the surface. The susceptibilities of the nervous system, however, in this direction differ, as we all know well, very greatly in different individuals. These differences are hereditary, and may easily become the possessions of families or of race. Not only do individuals differ in the degree of reflex susceptibility, but they also vary much as to the special tissues or organs which are most prone to suffer under it. Thus, some catch cold almost solely in the mucous membranes of the nasal passages and pharynx; in others, the tonsils, throat, and larynx are more prone to suffer; in others the bronchial mucous membrane; and in others the stomach and bowels, or even the liver. Although I shall admit rheumatism to the rank of a universal diathesis and place it for the present in this respect side by side with scrofula and catarrh, yet in doing so I shall have to suggest, as indeed I have repeatedly done, that rheumatism after all is only the catarrhal diathesis affecting the joints. Let me state a few general facts respecting catarrhal affections, and then pass on. First, it is a great mistake to imagine that only those of delicate constitutions, and accustomed to much protection from weather &c., are liable to catch colds. Farm labourers and others engaged in laborious out-door pursuits, often show this susceptibility very definitely, and suffer very severely. My impression is, however, that the peculiar degree of susceptibility which causes its possessor to experience slight catarrhal symptoms on every little variation, accustomed exposure is rarely reached in them. They take cold, but seldom, and when they do, it is in connection with some exceptional cause, and the catarrh develops with exceptional severity. I have, however, met with some remarkable instances of extreme development of the catarrhal diathesis in those who are constantly out in the open air. Especially well I recollect an apparently robust farmer, who could do anything he liked out of doors, but who could not sit in a carriage with an open window, or for ten minutes with his feet on a stone floor, without catching cold. It is a general law of all catarrhal affections, and well recognised in the experience

of every one, that they are spontaneously curable, but very liable to recurrence.

All forms of catarrh pass off spontaneously after awhile, and in many persons their duration is tolerably regular, and the period of immunity often keeps to the same average. When we find the results of a catarrhal inflammation threatening to become lasting we feel sure that the diathesis is a complicated one. It is one which very early mixes itself up with other forms of ill-health. We define scrofula to be a state of solid tissues, and more especially of the lymphatic system as a whole, in which there is peculiar proneness to chronic inflammations resulting in products more or less peculiar and specialised. Modern discoveries will perhaps lead us to believe that those specialised products are usually accompanied by the presence of particular organisms which are neither part of, nor derived from, the original tissues. Be this as it may, we shall have to study the scrofulous diathesis and the predisposing causes of scrofula just as before. We shall still have to ask what are the conditions which favour, or otherwise, the development of the bacteria in question. Even the firmest believers in the new facts admit this. Looking, then, upon scrofula as a permanent and heritable condition of the tissues favouring chronicity in all inflammatory processes and directions towards more or less specialised ends, it is easy to see that in such individuals catarrhal attacks may depart from their usual type, and may not show their natural tendency to spontaneous disappearance. As a matter of fact, we are only too familiar with the danger of catarrhal attacks in scrofulous subjects.

OUT-DOOR VERSUS IN-DOOR MATERNITY CHARITIES.

By J. E. BURTON, L.R.C.P. Lond., M.R.C.S.,
Physician-Accoucheur to the Liverpool Lying-in Hospital.

A SHORT time ago circumstances led me to institute an inquiry into the relative maternal mortalities of in-door and out-door maternity charities. I confess that at first my inquiries may have been rather vague and undecided, and it was not until a considerable number of facts had been ascertained that I decided to limit the inquiry to labours since the year 1875. My reason for doing this was that since that date a sufficiently large number of figures could be collected to make them of scientific value, and that they would have the further advantage of embodying the most recent advances in prophylaxis and treatment in childbed. It would have been very easy to multiply figures by going further back in time; those brought forward at the memorable discussion at the Dublin Obstetrical Society by Dr. McClintonck and others might have been made use of. I have, moreover, a very considerable array from various countries; but, unfortunately, they are absolutely valueless as far as the present inquiry is concerned. They represent the maternal death-rate in childbed in past years, and in the various localities in which they are collected, but have no bearing whatever, or only the most trifling, on the death-rate of the present era. Of what use is it to quote McClintonck's figures for or against the figures of last year? The inquiry was limited almost exclusively to the United Kingdom; not that I would not gladly have availed myself of recent data from any reliable source, but the difficulty of collecting facts, always great, becomes much greater with increase of the area from which they are gathered, and I was hopeless of getting reliable statistics from abroad within a reasonable time. (a)

I will now proceed to give the figures, and leave whatever remarks I have to make until the facts are before

(a) Since the above was written, the editor of a German medical weekly wrote me as follows regarding the difficulty of obtaining accurate statistics from lying-in hospitals:—"I am sorry I cannot meet your wishes. Either the administrations of the hospitals will not give the information, or, if willing, cannot immediately, and I doubt if, generally, the accounts can be given in a satisfactory manner. Here, as elsewhere, the fear is great to publish the true statements if in any way they might throw light on a bad situation."

the public. They have been obtained from eleven out-door and twelve in-door maternity charities.

The above tables comprise reports from nearly all the large lying-in charities in the United Kingdom. The Coombe Hospital is indeed conspicuous by its absence, but repeated applications on my part failed to call forth the desired information; the returns of the numbers of cases treated were procurable, but nothing that could be of value in the present inquiry.

Even a cursory glance over the table will show the enormous difference between the maternal death-rates in the two classes of charities—that in the in-door table being more than six times greater than that in the out-door; and naturally the first question that springs up is, are the figures correct, or even substantially so? Many will deny that they are, and have done so already. The *Lancet*, in that calm, judicial manner so becoming in the aged, says that it is mere "trifling" to bring such figures forward. Others have said that there must be some grave error in them.

We may safely premise that the results, as far as regards in-door charities, are correctly given. So long as they make such a very poor show no one will suspect the favourers of these institutions of wishing to make them appear worse than they really are, so that we may accept them as being tolerably exact. Besides, as a rule, patients are kept in hospital, and thus under supervision, until the termination of the case, they are either dead or convalescent before they leave the hospital, so that there is no great difficulty in keeping an accurate record of the results obtained.

With out-door maternity charities, however, the case is different. Here the cases are not under such strict supervision, and it would seem easy for errors to creep in. Consequently, some sort of guarantee is required that the results published are as good as they seem to be. If it can be proved that the figures in some of the most successful of them are correct, and thoroughly reliable, it will be at least *prima facie* evidence that the others are, or at least it will prove their possible correctness, for what has actually occurred in one place may at least be possible in another.

As the Birmingham Charity stands first on the list, we will take it first. The authorities of this charity claim that the figures given are absolutely correct. The annual report for 1880 says, "the state of health of every mother is ascertained thirty days after delivery;" and the report for 1881 says, "the state of health of every mother is ascertained and reported on by our midwives thirty days after delivery." As further showing the care with which these statistics have been compiled, I may add that the report gives three cases as transferred to the dispensary at the expiration of the thirty days, and that one of the three died of phthisis six weeks after delivery. I am quite aware that many medical men who are practising in centres where such excellent results seem unattainable will not believe these figures, but many of us whose lots are cast in more pleasant places, obstetrically speaking, see nothing incredible in them; nay, more, we expect good results.

Next comes the Liverpool Ladies' Charity, and although I cannot vouch for the absolute accuracy of its statistics, I can give my reasons for believing them to be correct. In case of difficulty or danger of any kind showing itself, an assistant medical officer is called in, whose duty it is to continue his attendance till the termination of the case. I have known them to attend for more than the thirty days usually considered as the puerperal period. In all my thirteen years' connection with the charity I never personally knew of a case in which an outside medical man was called in, except as the temporary substitute of the officer of the district. The objection made that a case may apparently be convalescent, then take ill and die without the knowledge of the officials of the charity is again groundless. I have questioned our midwives on this point, and they deny the possibility of such a thing occurring. The reason for their confidence is this: Liverpool is doubtless a large city, and it seems an easy thing for a woman to be taken ill in an obscure street and

nobody be the wiser for it. But all things are not what they seem. For our Charity purposes the city is divided into eight districts, and a midwife works her own district, and no other. There are six assistant midwives, sometimes one to one district exclusively, sometimes one to assist in two or even three districts. The midwife's district will still be sufficiently large, but as a matter of fact, her duties do not carry her over all of it. The class of people amongst whom her work lies are concentrated in one particular locality of the district, in one or two streets or squares with their "courts" and alleys, so that the midwife knows every face, every family in her district, for to her they are just a little village community. They (the midwives) think, and I think with them, that for a case of illness to occur and prove fatal without their knowledge is almost an impossibility. Again, during the present year, up to date of June 1st, the assistance of an assistant medical officer has been required 19 times. Now, if a charity case proves fatal at all, it will necessarily be one of the number that has required medical assistance. This reduces the cases in which a fatality could or would be likely to occur to about 45 per annum, and dividing this number by eight, gives the number that each midwife would have to be particularly careful about.

Moreover, as far as my own observation goes, I believe the figures to be correct. During the eleven years in which I was an assistant medical officer to the Charity, in which I had the supervision of at least 4,000 cases, only five deaths occurred from puerperal accidents; two from placenta prævia, one from concealed accidental hæmorrhage (dead on arrival), one from shock and hæmorrhage after delivery (cancer of uterus), and one from post-partem hæmorrhage. There has not been a single case of craniotomy or cephalotripsy (a) in my district, and our Charity does not extend to unmarried women, so that it will be seen, upon the whole, that we have a pretty favourable field for practice. Such being the case, we may expect favourable results.

We now come to the City of London Lying-in Hospital. The secretary of this institution, in kindly furnishing the information desired, made the following remarks:—"That no record of death in the out-patient department was kept after the ninth day, whilst a considerable number of deaths took place in the hospital after that day. That there was a larger proportion of primiparæ in the hospital than in the out-patient department. That difficult cases are admitted from the out-patient department. All these points are certainly very proper to bear in mind in making a comparison between the two charities. The records from the General, Rotunda, and Queen Charlotte's Lying-in Hospitals are only for one year.

The Newcastle-on-Tyne Lying-in Charity is mixed, partly extern and partly intern. As the intern cases number only about 20 per annum; there can, of course, be no "aggregation" of cases, and it may, for the purpose of this inquiry, be considered altogether as an out-door charity. The death-rate here is 1 in 652, and its accuracy is sufficiently vouched for by the fact that no midwives are employed, but that all the work is done by the medical officers.

The results in Glasgow are not sufficiently startling to challenge the questioning attention of the firmest believer in the heavenly mission of lying-in hospitals.

From the British Lying-in Hospital I can only give the figures; no explanation came with them.

Next comes the Royal Maternity Charity, Finsbury Square, with its 13,515 cases in four years, and 41 deaths, or 1 in 300. These figures are "carefully collected" from

(a) With regard to craniotomy and cephalotripsy, another fact should perhaps be mentioned. Dr. Sigismund Lewis, of this city, a good many years ago, introduced a very formidable looking pair of midwifery forceps. They weigh a little over 2lbs. Their length is about 18 inches. From fulcrum to tip of handle, 7 inches; from fulcrum to tip of blade, 11 inches; greatest distance between blade, internal measurement, 2 9-16 inches; external measurement, 2 15-16 inches. The blades are, therefore, nearly 3-16 of an inch thick. They have the ordinary double curve. As may be imagined from the description, they are instruments of enormous power, and doubtless often take the place of the cephalotribe.

the "monthly reports;" they are from "monthly reports carefully compiled by our secretary, Mr. Jno. Long." Mr. Ernest Hart has evidently been a believer in the accuracy of the statistics of this charity, for in the *British Medical Journal* of January 4th, 1879, he is reported to have said: "The comparison of the death from childbirth in the Royal Maternity Charity with those in all England was very striking. The mortality in childbed in all England was exactly double that of the mortality in childbed of the Royal Maternity Charity, which relieves unselected cases of poor women in their own homes."

The *Lancet* of April 27th of the same year throws no doubt on the accuracy of the statistics, and still less, speaks of them as "trifling with the subscribers." It says, "in the whole of London last year the deaths of women from puerperal causes were nearly double the rate of mortality among the cases attended by the Royal Maternity Charity, in which the deaths of women from puerperal causes was only in the proportion of 2 per thousand women delivered." As a guarantee that the statistics are accurate, the report (1878) says: "A report of the state of health of mother and child being required monthly from every midwife, and a minute record of every case to which the Charity's physicians are called, with the nature of the illness and its result, is faithfully kept."

The Manchester St. Mary's Lying-in Hospital is also both an intern and extern lying-in charity, but as in Newcastle, the cases admitted are so few that there can be no "aggregation" of maternity cases, for which reason it has also been classed as an extern maternity charity, for the question we are considering is not, strictly speaking, hospital? or home? but aggregation? or isolation? The report for 1879 says: "The period allowed for computation extended over a month from the time of delivery." It will be evident from the foregoing that the figures have been collected carefully, and this being so, one may be fairly entitled to believe in them without laying oneself open to the charge of being innocently credulous.

Taking the Birmingham, Newcastle-on-Tyne, the Royal Maternity, and the Manchester St. Mary's Hospital lying-in charities—institutions that guarantee the accuracy of their reports—we have 28,800 cases with 79 deaths, or 1 in 364, a very near approximation to the rate given in the tables.

As these figures are clearly reliable, we may accept them, and consider, then, that the death-rate stands as follows:—

In out-door maternity charities, 1 in 363. In in-door maternity charities, 1 in 56.

(To be continued.)

THE DISEASES OF EGYPT, FROM OBSERVATIONS MADE DURING THE BRITISH EXPEDITION IN THAT COUNTRY UNDER SIR R. ABERCROMBIE, K.C.B., IN 1801.

THE following additional particulars to those given by Surgeon-General Gordon in the *Medical Press*, of July 19th are communicated by Dr. J. Black, F.R.C.S.E., and extracted from the history of that campaign by Col. R. Wilson, published in 1803, and will be read with interest at the present juncture.

In no country are the inhabitants afflicted with more dreadful disorders, many of which must be attributed to the vices of the people; yet the most fatal proceed from causes which civilisation cannot altogether control.

The Plague as being the malady which occasions the greatest alarm amongst those who have never been immediately acquainted with its nature, ranks as the most fatal of all distempers. This epidemic fever was long supposed to have been brought from Turkey in the ships charged with old clothes which constantly came to Alexandria for a market for their sale.

But these reasons cannot any longer be maintained, since the plague has been generated annually in Egypt, during the last four years, 1797-1801, though no such communication had been possible, and has even commenced in Upper Egypt.

The plague commences when the waters of the Nile begin to fall lower in October or November, and continues during the winter and spring months when they are at their lowest in the Delta, and ceases to be fatal almost to a day or so after the 17th of June, when the waters are at their lowest, and when the river is supposed to begin to receive its first increase of water again from Upper Egypt. As the waters retire from the surface of the country they had inundated, a rich slime of considerable density is left, which forms a soil so productive as to render Egypt the most fertile land in the world. This slime, subjected to natural laws, is no sooner separated from its principle of action, then *corruption* ensues, and continues during the autumn and winter until all the putrid juices are exhaled by the heat of the sun into the air. The ground is then, at last, left perfectly dry and brittle, with the fissures in it, and the atmosphere at this time, in spring, ceases to be tainted, and the plague throughout Egypt disappears. It is contended that the plague is like all fevers, more or less infectious, according to habit of body, and duration in bad air, and that the disease hangs only in the atmosphere or breath of the afflicted patient, and is not to be conveyed by touch on a third person. Since the French Expedition to Egypt great discoveries have been made as to the properties of the plague by the ability and boldness with which numerous cases have been treated.

Assalini asserts that he found by observation in the French army, that if a battalion infected with it left its cantonment for another, the distemper not only ceased in that corps, but that no one having communication was exposed to danger. Nor did the phenomena end here, for even if the battalion that occupied the post which had been left by the diseased battalion, had quitted the place in ten days, no symptoms of the disorder ever appeared amongst them.

As a proof of the plague being confined to the atmosphere, he mentions several remarkable cases at Jaffa of men who were confined for the plague in the hospital of that town, and had escaped into the Desert. They endeavoured to reach the army, but, finding the attempt impracticable, returned again in three days, and found themselves perfectly recovered.

This extraordinary cure induced Assalini to encourage a removal from Jaffa whenever the first symptoms were discernible, and every one on whom he could prevail to adopt this advice soon became convalescent. At Aboukir the dead bodies of the Turks, French, and English might have occasioned the putrid miasmata containing the sources of the disease. Medical men should know that at Aboukir the plague continued longer than in any part of Egypt, as the sun there, on account of the sea breeze, did not possess sufficient power to dissipate all the mephitic exhalations (also due to the dampness of the air on the coast). The facts must also be stated that the English and Turkish armies, which marched to Cairo, passed through a country where the plague filled almost every village. They communicated, without any precautions, in the most intimate manner with the natives, and established their ovens at Menouf, where the plague raged violently. The Turks even rifled the diseased persons in the best houses of Rahmaneh, and at Cairo even dug up the corpses recently buried, and yet no individual instance occurred of the malady in the armies.

The troops, however, who remained stationary at Aboukir were severely afflicted, of whom 173 died out of 380 cases; but neither at Rosetta nor Alexandria did the fever show itself.

In Egypt, where the villages approach within a quarter of a mile of each other, some were exempt from this malady, whilst the most neighbouring were decimated. So common is this circumstance that the inhabitants particu-

larise to Europeans those villages in their districts in which, during the season, the plague has appeared, and yet did not refuse themselves to enter into them. Nor, indeed, did the English hesitate, although frequently the dying were laid by the gate through which they were to pass in.

When the plague has been most virulent in Cairo, the inhabitants of the Citadel above have often been totally free from any infection, although having daily and promiscuous communication with the dwellers in the city below. This partial infection of the atmosphere can only be attributed to the different degrees of foetid matter left on the ground producing different quantities of putrid miasmata, and the direction of the winds at the place wafting them in different directions.

In Cairo last year (1800) 40,000 people were stated to be infected with the plague, in a population of about 240,000 estimated; and many of the French garrison died in that city, although the disease was treated in their hospitals with great ability. The celebrated Desgenettes was chief physician to the French army, and the inspection of his hospital obtained universal admiration, particularly the great one at Cairo.

In Upper Egypt, 60,000 of the inhabitants, estimated at 750,000, perished during the same season of 1800, and whole villages of people were swept off, and they remained abandoned when the Indian army descended the Nile, July 29th to August 8th, 1801. At the same time, many instances occurred when the nearest villages had not possessed a case of the malady. Dr. Young, I.G., states in his return of sick, p. 132, that the deaths in hospitals chiefly fell on the orderlies, nurses, and other servants; but this observation cannot controvert the position that the plague is not more contagious than other fevers. The servants attached to a hospital, by continuing in a tainted atmosphere, must certainly be subject to maladies produced by bad air, and these instances afford proof in favour of a doctrine important to humanity and military service.

Egypt, in the possession of a Power who felt interested in her prosperity, might, in the course of years, calculate on this disorder being altogether annihilated, or the pernicious influence so corrected as no longer to possess the same injurious properties.

The introduction of lime, the use of coals for firing, the paving of the streets in cities, the formation of solid roads, the whitewashing of the apartments of houses, the draining off of all stagnant waters, the use of well-burnt brick instead of mud in buildings of the villages might be the means, in time, to correct the corrupted exhalations of the soil. Attention to cleanliness of person and dress would promote considerably the above operations. Until that too remote period arrives, the abilities of medical men have discovered medicines which check the fatality, if they cannot always cure it. The embrocation of oils is found to be very beneficial, and mercury will generally produce favourable effects if the disorder has not gained already too much progress.

Inoculation.—Dr. Whyte, an English physician, determined to discover if this malady, so destructive to a large portion of the globe, could not be checked, or rendered less virulent, by the introduction of inoculation. Resolved to become the patient of his own speculation, during the time the plague raged again at Rosetta, towards the fall of the year (1801), he inoculated himself with matter taken from the buboes of an infected person. The attempt failed twice, but the third proved fatal. In three days after the symptoms appeared he died, falling a much-to-be-lamented victim to a disinterested zeal, benevolently and intrepidly directed for the benefit and happiness of the community.

This catastrophe may for some time operate against the prosecution of a very interesting theory, yet in the detail of this case there are many incidents which will hereafter excite the attention and enterprise of the inquiring mind. The fact may very soon be incontrovertibly established that this fever is local, and excited

by the state of the atmosphere, in its progress not contagious, which will be very consolatory to humanity. It will be particularly important to ascertain this at a moment when the countries most subject to this dreadful pestilence are about to be more intimately connected with the States of the civilised world.

Ophthalmia.—The period no sooner arrives when Egypt for a season is relieved from the plague at the middle of June, than another malady succeeds immediately, distinguished by the name of ophthalmia, and prevails during the summer months before the period of the inundation. The effects of this disease are much more terrible than those of its precursor, the fever called the plague, which is not attended with any corporeal pain, torpor tranquillises all sensibility of mind, and the hour of dissolution is expected with apathy.

In the case of ophthalmia, the anguish of the affected part is acute, nearly to delirium, whilst the unhappy patient retains a consciousness that his agonies probably may terminate in the loss of organs precious as existence.

The quantity of the blind in Egypt is prodigious, nearly every fifth inhabitant has lost one eye, estimated at 600,000, out of 3,000,000 of a population in 1801, and many have lost both, and all the children have sore eyes, and the Europeans do not escape the disease.

The French at first had more than two-thirds of their army (21,454 out of a total of 32,180 estimated) according to their own report, affected with this malady. The English troops during their short stay have suffered considerably, 160 having become totally blind, and 200 having lost one eye irrecoverably—360 cases out of a total 19,424 of all ranks.

The disorder is believed to originate in the nitrous and malarious particles emitted from the ground by the force of the sun, which are of a quality so pungent and penetrating as to injure the fine vessels at the corner of the eye. The acrid and burning dust flying in the atmosphere irritates still more the already affected part. The reflection of the sunlight from the grey soil, the heat of the air, and the livid light of the sky, tend to weaken the sight, and at last occasion that excessive inflammation denominated ophthalmia.

When the actual ophthalmia has taken place, the patient suffers the most *excruciating pains*, which are described as if the balls of the eye were on fire, and the points of needles perpetually pierced into them.

The abscess or tumefaction formed under the eyelids discharges a considerable quantity of moisture, which frequently vitiates into matter, every membrane swells, and the whole eye becomes frightfully distorted.

The children in Egypt, from the barbarous inattention of their parents, have, from the earliest infancy, at the corner of their eyes a great quantity of little insects continually settled, which keep the vessels in a constant irritation, and finally burrow themselves into the interior coating of the eyelids. Scarcely will this assertion be believed, nevertheless the fact is evident that all the mothers are guilty of this inhumanity, negligence, and uncleanness.

The advent of the malady is sometimes extremely sudden, which induces the supposition that checked perspiration frequently and severely contributes to produce the disease. In a few hours after the inflammation has attained an alarming strength, to which no precise crisis can be anticipated.

With some the disorder lasts only nine or ten days, in others the patients have suffered for months, and unfortunately there is no security, even after perfect recovery, against an immediate new attack.

Ophthalmia is endemic to Egypt, and its extirpation can scarcely be expected, but an acquaintance with all the different cases has enabled the European physicians to discover remedies, which have rendered this disease in some degree less fatal.

Opium was found then the best application (probably in its various forms of vinum opii, laudanum, and opiate fomentations, powders and pills, internally, &c.

Lately, some extraordinary cases have appeared, which prove that a certain form of ophthalmia is highly infectious occasionally.

Dysentery.—Ophthalmia and dysentery are twin evils generating in summer, and expiring in autumn together, but the latter, so destructive to armies in Europe cannot be deemed, however, more pernicious to them in Egypt. The returns of sick by cases of dysentery in a campaign where the climate is moist, and the ground damp, will be found to exceed considerably those of cases of the same malady in this dry soil and climate, where the damp of rain seldom penetrates.

There is, however, in Egypt, particularly on the Isthmus of Aboukir, every morning an exhalation in the low lands where the date tree grows, of an extraordinary dense fog, which must be extremely noxious. But troops would seldom be obliged to encamp in and expose themselves to the dangers of such situations. Some have attributed to the Nile water the cause of this disorder, which is erroneously imputed to it, unless excessive quantities are drunk, when any water would be equally unwholesome.

This water certainly at the season of the year when dysentery appears, becomes extremely thick, and even foetid in smell, as a tumbler-glass full allowed to stand and settle for five minutes would yield at least one-third of slimy mud. The operation of this *sediment* is, however, to be deemed rather salutary than otherwise, and a little vinegar or spirits infused would always correct any bad effects. With more injustice do others affirm that the *bad diet* is a principal cause of dysentery, for in Egypt every thing which is eaten tends to promote acrimonious humours by its deleterious qualities. The poultry of the country from being unnaturally forced in ovens, seem to have the sources of health and growth dried up. They never exceed the size of a pigeon, their bodies yield only skin and bone, between which are lumps of rank fat, extremely nauseous and unwholesome, and their eggs are very heavy to the stomach, and often occasion sickness when eaten. The Emperor Hadrian being angry with the Egyptians wrote thus in a letter, "I wish nothing more to befall them than that they may feed on their own pullets, which, how they hatch, is a shame to speak of." Buffalo meat is indigestible, and the mutton not very good, and the oily food of the common inhabitants still more weakens the intestines, and produces a disposition to overflow of the bile.

Another cause of dysentery is checked perspiration as well as drinking of bad water, for the soldiers crowded into the Nile to bathe when their bodies were pouring out streams of moisture, quite indifferent to the consequences to themselves, of which they were so frequently warned. On the march to Cairo from the coast nearly thirty soldiers were drowned when bathing in the Nile.

At night a damp air chilled those who did not secure themselves by a covering; and during the march to Cairo frequently fifty men per day, out of a total of 4,412, who were seized with the malady, were obliged to leave the army. The impression of heat seems also to have had a considerable influence in maintaining it, since those sent to Rosetta, near the coast, or who were transferred on board ship, very soon recovered. The sea air braced up again immediately the systems which had become too much relaxed in the interior of Egypt. An attention to dress in this complaint is extremely necessary, both as a preventive and as a cure. Flannel shirts, and pantaloons made of woollen cloth, should be worn, and the gaiter and breeches are the worst possible appointments for soldiers in a warm country. At night the damp penetrates to the skin through the buttonholes of the dress, even with the most prudent precautions.

Who does not know that a soldier wearied with marching, which occasions a swelling of his limbs, increased by the tightness of his dress, almost always, for the sake of ease and rest, removes every close dress, and exposes to the air his legs and knees during the night when lying down?

Cutaneous diseases.—A skin disease prevails very generally in Egypt during the rising of the Nile (July, August, and September), which is extremely disagreeable, but scarcely ever fatal. The itching is barely endurable, but the appearance of this heat eruption is considered as an indication of health, and cooling physic soon removes it altogether, so that the complaint may be deemed only an inconvenience, not amounting to a malady. An officer imprudently bathed three times in one day when the rash was strongly out, and thereby threw into the system what Nature wished to reject, and he died in twelve hours afterwards. Such instances, however, occur in similar harmless complaints in Europe, affording melancholy evidence of indiscretion, giving to disorders an inveteracy of character.

A vast variety of more severe diseases are common, and seem to have a peculiar character in that country, but, as not immediately affecting the English army, they shall only be classed under their different heads.

Common diseases.—Leprosy of the worst species; elephantiasis, very common and of the worst sort, in which the legs are swollen larger than a bed bolster; hernia, extremely frequent; syphilis of the most malignant kind; dropsy, sore heads, worms, liver complaints, all very frequent.

Minor plagues of Egypt:—

Rats in extraordinary abundance, which the inhabitants of some villages near Rosetta eat.

Flies and other insects, numerous beyond credibility.

Fleas in such quantities that in twelve hours clean linen was covered with thousands of spots of blood.

Lice of every species. The Mameluke Boys even would think it no disgrace to employ themselves publicly in picking them off their persons.

Mosquitos and gnats.—Their bite was particularly venomous, especially near Rosetta.

Scorpions and centipedes.—The sting is painful, and produces tumours, but is not dangerous.

Locusts very destructive to agriculture.

Many of these disagreeable animals, the Egyptians may say, are also inmates of Europe; but in no other country are they so numerous or so voracious as in Egypt.

Special.

THE BRITISH MEDICAL ASSOCIATION AT WORCESTER.

THE COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES BY MEDICAL MEN.

FOR the first time this question was discussed at a general meeting, after due notice had been given, with the result which those who had urged the necessity of discussion anticipated, viz., a condemnation by a very large majority of the principle of compelling medical men to report. The result was all the more significant from the fact that Mr. Hastings was present to defend his own Bill, and that he was backed by a large number of medical officers of health, prominent among whom was Dr. Littlejohn, of Edinburgh. A preliminary discussion having taken place in the Public Health Section on the 10th inst., on a paper read by Dr. Carter, of Liverpool, the question came up for decision at the general meeting held at 11.30 a.m. on the day following. Much interest had been excited, so that the attendance was very large. The proceedings were commenced by the President reading a memorial, signed by sixty members, which had been agreed upon at a meeting held at Liverpool, presided over by Dr. Carter, praying that a time should be set apart for the discussion at Worcester; and he then called upon that gentleman to open the discussion.

Dr. CARTER pointed out that the Public Health Act of 1872 had been loyally accepted after full discussion in Parliament, and had been productive of a large amount of good, about a quarter of a million of people being alive at the end of the first decade of operation who but for it would probably have died; that the principle of the Act was to make

every medical man the medical officer of health for the households which he attended, but that almost immediately after it became law medical officers of health began to clamour for another Act founded on novel principles, of which compulsory notification by medical men, compulsory removal of patients to hospital, and compulsory closure of shops were examples. These principles had been adopted in some few local Acts for a long enough time to judge practically of their results. They had often been introduced in a surreptitious manner into Bills under cover of titles which afforded no presumption of their character, as for example, into the Nottingham Bill, which was to enable the authority to "construct new gasworks, repair a road, and other purposes," and hence had not been fully debated in Parliament, as the General Act had been, and had not received, as it had, the sanction of public opinion. Bolton had been put forward by Mr. Hastings and many others as a remarkable example of the advantage of the Act which embodied these new principles. This town had had a larger experience of it than any other in the Kingdom, and what was the result? Why, that taking the arbitrarily selected number of years, and the very diseases relied on by Bolton for proving her case, it was found that Liverpool, which for many reasons was more liable to infectious diseases than any other city of the United Kingdom, had progressed nearly half as fast again without any such Act as Bolton had with it; and that if a similar comparison was made between the latter town with its Act and the country generally without it an exactly similar result was discovered—Bolton lagging far behind the country in the race of sanitary improvement. Dr. Carter further showed that, according to returns given in the *British Medical Journal* for Jan. 7th, 1882, the mortality of Edinburgh had increased from 20·24, the average of four years before it acquired compulsory powers, to 20·55, that of the two years since; and that of measles, which Dr. Littlejohn had specially mentioned as showing the practical advantage of the Act, 440 cases had been reported in February of the present year, 1,118 in March, and 1,239 in April, figures which in his judgment simply demonstrated the impotence of the Act to deal with the disease—nearly 3,000 half-crowns having been disbursed in consideration of this proof of its powerlessness. He next gave examples direct and inferential of concealment of infectious disease in some of the towns possessing compulsory powers through dread of the publicity which would follow the calling in of a medical man. He cited the enormously high death-rates from typhoid fever in Bolton and Blackburn as showing either that many cases were concealed, and thus the death-rate made to appear exceptionally high, or else that the application of the powers provided by the Act was very fatal to the individuals attacked. Dr. Carter then gave a number of examples of conflicts between medical officers of health and general practitioners, leading in several instances to the imposition of fines on the latter, and causing in all cases a spirit of bitterness and antagonism between the curative and preventive branches of medicine, which must be detrimental to sanitary progress. Among other instances he quoted from a letter of Dr. Bond, in which that gentleman stated that he "should be afraid to say how many deaths came under his notice registered as having occurred from diphtheria, croup, and laryngitis which he had good reason to believe were simply cases from imperfectly developed scarlet fever," and remarked that if the law of Bolton had been in operation in Dr. Bond's district he would have been morally bound to institute proceedings against all those medical men of the correctness of whose diagnosis he presumed to be the judge. Lastly, he showed petitions signed by many hundreds of medical men from Liverpool—including the name of the President elect of that Association—and from Ireland, brought specially over from Dublin by Dr. Jacob, against the principle of compulsory notification by medical men, and proposed, in order to test the true feeling of the Association on the matter, that a plebiscite should be taken.

This was seconded by Dr. EWING WHITTLE, of Liverpool.

Dr. LITTLEJOHN moved as an amendment,

"That in view of the unanimous opinion of all competent sanitary authorities that notification is the indispensable basis of action for arresting the spread of infectious diseases, and of the general testimony as to the satisfactory operation of the Acts already passed to make such notification compulsory, this meeting declines to withdraw the approval which the Association has repeatedly expressed in favour of urging Parliament

to make the notification of infectious disease generally compulsory, under such conditions as may appear to be, after due inquiry, best calculated to protect the public health." He objected to a plebiscite on the ground that those from whom the vote would be taken would know nothing about the matter; gave the history of the Edinburgh Act; denied the accuracy of the figures of the Edinburgh correspondent to the *British Medical Journal*, which showed a rise in the general mortality of that city since its Act had been obtained, and urged the adoption of the amendment by the Association.

The amendment was seconded by Mr. EVERETT, of Sydenham, and supported by Mr. GEORGE HASTINGS, M.P., who spoke of the unanimous approval of the twenty-three sanitary authorities in England who had adopted compulsory powers as showing their practical advantages, and mentioned that none had appeared before the Select Committee to oppose the powers, and that when another Act to compel medical men to perform certain duties,—viz., to register the cause of death—had been proposed it had been at first opposed, though now acknowledged to be of great advantage.

Dr. FITZ-PATRICK, of Liverpool, pointed out that Mr. Hastings was wrong in nearly every particular; that no medical man could be compelled to give a certificate of death; that so far from there being no opposition before the Select Committee, Dr. Alfred Carpenter had specially appealed to be heard against the compulsory clauses, but had been refused on the ground that he had no *locus standi*, and that the supposed assent of the twenty-three towns was merely the expression of the opinion of their medical officers of health, who, having asked for an Act, would scarcely be likely at once to admit its failure. He went on to show the fallacy of Dr. Littlejohn, who constantly spoke of "the Act," as though the Edinburgh Act and those of the English towns were identical, when, as a matter of fact, they were strikingly dissimilar, most of the latter excluding measles, and allowing only one report from a single house within thirty days, while Edinburgh included that disease, and paid for every case, even if there should be a hundred of these in some of those houses to which Dr. Littlejohn had alluded as containing sometimes as many as 120 inhabitants. He remarked that his opposition was based on the ground of these powers being opposed to a sound public footing, and that it would be equally great if a fee of a guinea were offered instead of half-a-crown; but that, without speaking offensively, he thought it not impossible that the national love of the bawbee, and the ease with which, owing to the peculiarities of the Edinburgh Act to which he had alluded, many of those could be acquired by his Scotch friends, had had much to do with allaying their opposition.

The amendment being put, the President declared it carried.

A further amendment was then put by Dr. MAHOMED,

"That this meeting earnestly desires compulsory notification of infectious disease, but it wishes to express its opinion that the compulsion to notify should be placed upon the householder as his duty as a citizen, and not upon the doctor."

This was seconded by Mr. HUSBAND, of Bournemouth, and carried by a very large majority; and as no further amendment was forthcoming, it was subsequently passed as a substantive motion with an equally large majority.

Dr. JACOB, of Dublin, who had attended for the purpose of taking part in the debate, and had brought a very numerous signed petition against compulsory notification by medical men from Ireland, was unfortunately summoned from Worcester to London to give evidence before a Select Committee of the House of Commons.

A PARIS patent-medicine man describes his chloral syrup as bottled sleep—*le sommeil rendu en flacon*. Puffing as a fine art can go no farther.

THE latest additions to chemical nomenclature are the following, which have been transcribed by a recent contributor to one of the Paris papers:—*L'Arhomononitrodiphyldiacetylène*, *Diparatolyldiazophénylurée*, *L'Ethyléné-tetraméthylidiphénylphosphonium*.

WEDNESDAY, AUGUST 23, 1882.

THE POCKET ARGUMENT AGAINST MEDICAL REFORM.

It has long been customary for satirists to exercise their most peculiar powers at the expense of a certain well-recognised attribute of the Scotch mind, and to draw conclusions irresistibly suggested by the national weakness usually associated with those who regard the thistle with especial reverence. Without applying to Scotchmen the full significance of the *auri sacra fames* motto, we may yet ascribe to them a willingness to grasp every pecuniary advantage they can by any right lay claim to; and this, too, in whatever relations they may claim to be placed with respect to dispensers of the “almighty dollar.” At the present time we are compelled to pay heed to this trait in our friends over the border, inasmuch as it is assuredly exerting its influence in directing the attitude of the profession in Scotland towards the scheme for medical reform now agitating the country; and the most striking proof that has lately been forthcoming of the justice of this assumption is to be found in a lengthy address with which Professor Fraser gratified graduates in medicine at the recent “capping” ceremony at Edinburgh. Among other subjects, Professor Fraser naturally dwelt on the report issued a short time since by the Royal Commission on the Medical Acts Amendment. The tribute which he was from his position called upon to pay to the excellence of the University he represented, was most rigorously rendered, and full credit assumed to it as a

pioneer in all that has tended to elevate the profession in all parts of the globe. Moderate laudation at such times is excusable, but it will need more than a little urging to convince persons who do not hold Prof. Fraser's exaggerated opinions of the complete justice of his exactions, and as they necessarily led to the utterance of prophecies at the least improbable, it may be doubted whether they were altogether wisely ordered. But let Prof. Fraser speak for himself; his own words are:—“The Commission, however, has recommended a scheme which is not in harmony with the views of the Scottish Universities. Stated in a few words, it proposes that a divisional board should be appointed in each of the three kingdoms; that the board should consist of the representatives of the Universities and corporations, and that, among other functions, it should be charged with the duty of regulating the education and conducting the examinations required for admission to the Medical Register, each existing medical authority retaining its right of conferring its special degrees or licences. This scheme, in the first place, would add three new examining boards to the nineteen now in existence, thereby increasing what has been urged as a fault to be remedied, namely, the superabundance of examining boards. It would establish three new authorities, whose examinations must be of the nature of mere pass or minimum examinations; but as they must be undergone by every practitioner, their low or minimum standard would undoubtedly affect the examinations, and in that way the education of all the medical schools in the kingdom. Freedom of teaching would be impeded, investigation and the advancement of medical science would be hampered, and the medical teaching of this country would be burdened by an incubus tending to reduce it to one uniform level of mediocrity. The contending interests of the licensing authorities, the existence in some quarters of evils demanding reformation, and the difficulty of effecting reforms without injuring the admitted excellences of many existing institutions, no doubt imposed a task of great perplexity upon the Commission, and their report reflects clearly the diversity of opinion which is everywhere met with, and the enormous difficulty of formulating a scheme which will harmonise existing differences.”

To many who have felt some faith in the possibilities opened up by the institution of a uniform examination standard, the distressful picture drawn in these sentences will strike dismay; but subsequent reflection may, perhaps, dull the keenness of their regret, for it should be remembered that these are the official opinions of a corporation that has little to hope for in the event of such a change as shall make its diplomas valueless, save as an ornamental addition to a usable qualification. In all that is said condemnatory of the proposed reform, it will be, above all, advisable to remember the circumstances under which exception is taken, and to consider the force of each objection raised. Professor Fraser's charge, that three new examinations will be added to those already existing, loses its force when it is seen that no one of all the nineteen now in operation will be able to take equal rank with the three new ones. None

but qualifications to which real value appertains, apart from the facilities they at present afford for registration purposes, will, in the future, have a chance of competing with *bona fide* evidences of superior attainments. Without entering into any invidious comparisons, it may be admitted that once the scheme of the Royal Commissioners regulates admission to the Register, an end will be put to the income derived by all but a small minority of the licensing bodies which now earn a respectable annual sum by the sale of licences. This fact cannot be hidden, and we may, without any excess of ill-nature, ascribe to it a good deal, at any rate, of the opposition with which the scheme is threatened by the Scotch corporations.

That sort of philosophy which can unconcernedly regard the advance of opinions whose triumph will annihilate sources of profit is not easily bred anywhere, and least of all can it be expected to penetrate to places where the pocket bias has so long held undisputed sway. It is a little astonishing, nevertheless, to be told that the evil of evils we are to suffer under the new management will be a depreciation of medical education in response to a reduced standard of examination. Even if this should be so at first, the remedy will very quickly supply itself, for the disproportion that must ensue between the men who gain the minimum qualification and those who pass other, ornamental, examinations, will be so considerable as to demonstrate the inferiority of the former as compared with the latter, and lead of necessity to the required amendment. In what respect freedom of teaching would be impeded it is difficult to understand, unless it be that Prof. Fraser has foreseen developments that do not appear probable to the rest of the world. It may be taken that the examination of candidates for a registrable qualification will be pursued on lines very similar to those along which not the least desirable of existing licences are granted; and if this be so, the teaching arrangements that suffice at present will not be more than enough to fit the coming needs. The incubus tending to reduce to mediocrity has existence mainly in the mind of its originator, who might advantageously explain at greater length the meaning of the picturesque sentence into which he incorporated the phrase. Assertions like it carry an audience for the moment, but unsupported they have little weight to emphasise them; and unsupported they are worthless. Dr. Fraser is right in one point, and that only; it is the conflicting interests of licensing authorities that impede reforms, and those interests are unfortunately all of the dollar description.

THE PROTECTION OF THE PUBLIC FROM VENEREAL DISEASES.

THE Committee appointed by the House of Commons to investigate the working of the Contagious Diseases Acts has—as our readers have been already informed—reported emphatically and decisively in favour of the maintenance and careful enforcement of these Acts. That Committee ought never to have been appointed at all. Already the subject had been more than once officially investigated, and from year to year the

working of the Acts had been subjected to the closest scrutiny, called forth by the persistent attacks upon the system made by professional agitators, goody-goody old women, and uneducated, though well-meaning, clergymen. Every means, from deliberate lying to ignorant misrepresentation, had been employed with a patience and constancy worthy of a better cause to discredit the law and the machinery now used to prevent the dissemination of venereal diseases; and newspapers specially devoted to this object (and to wheedling irrepressible old women out of subscriptions) had been printed from week to week, and industriously circulated wherever it seemed likely that credulity was to be found. Moreover, assertions were made and insisted upon which, if true, would justly have discredited the Contagious Diseases Acts; and statistics were cooked so as to appear to prove that those Acts were useless. These daily reiterations of statements, the falsity of which had been long since proved, aided by the clamour of the "Vigilance Committee for the Protection of Personal Rights" (a radical organisation which has for its object to create free trade in small pox—venereal—filth poison, &c.), worried a Government which was willing to purchase political peace at any price into this additional inquiry. Well! the syphilis-propagation societies had every favourable opportunity. They had a Committee in which their own partisans—Mr. Stansfeld, Mr. Hopwood, Mr. Burt, and others—had an influential voice; and they had unlimited facilities for producing evidence to maintain their own views. Their case has been fully and patiently heard, and the verdict is once again dead against them. The Committee was first appointed in June, 1879, and was continued by four subsequent re-appointments, so that the inquiry has extended over a period of upwards of three years. The subject was divided by the Committee into two branches: first, the hygienic effects of the Acts; and, secondly, the constitutional, moral, and social aspects of their principles and administration. The conclusion at which the Committee arrived as regards the effects of the Acts on the efficiency of the Army is, that "out of 16·69 per 1,000 who would probably have been withdrawn from the efficient strength of the Army in the subjected districts, if they had not been under the Acts, 5·38 per 1,000 have been daily saved to the efficient strength of the Army by the operation of the Acts. To this saving ought to be added the gain to the service derived from the increased immunity of the men from the various debilitating and incapacitating disorders which, though not classed as venereal diseases, not unfrequently result therefrom." The Committee also report as their opinion that the Acts have had a beneficial effect in reducing the amount of venereal disease among the civil population, and in diminishing the virulence of the disease among the prostitutes in the subjected districts. They conclude by saying that the "extent to which the Acts have diminished primary and constitutional syphilis in the subjected districts appears of itself to your Committee to establish the hygienic utility of the Acts. The diminution of gonorrhoea in the subjected districts, attributable to the Acts, in the same period is less

considerable, but substantial." Under the second head of the inquiry the Committee carefully considered the objections raised against them by the opponents, and the advantages (other than hygienic) claimed for them by the advocates of the Acts. The conclusion at which they arrived was that the objections were not sustained by the evidence adduced in support of them. One of these appeared to the Committee so serious, that if it could be proved, it would be fatal to the maintenance of the Acts: "that virtuous women may be, and are, brought under their operation." They therefore spared no labour in probing it to the utmost, with the result that "the charges of misconduct brought against the police have broken down, and they desire to record their concurrence in the opinion expressed by the Royal Commission, 'that the police are not chargeable with any abuse of their authority, and that they have hitherto discharged a novel and difficult duty with moderation and caution.'" The Committee consider that the Acts are shown to have been beneficial by the diminution of prostitution in the subjected districts, and especially the diminution of juvenile prostitution, by the improvement of the physical condition of the women, and by the promotion of public order and decency in the subjected districts.

We earnestly desire, but do not cherish the least hope, that after this complete discomfiture, and after the teaching afforded to them by the witnesses before the Committee, the agitators for syphilis propagation will see that their premises are false, their conclusions incorrect, and their demands unreasonable. They will see nothing of the sort, inasmuch as they are, most of them, utterly impermeable to fact or reason, and some of them pecuniarily interested in keeping up the agitation. Those who live by the agitation cannot afford to be convinced—those upon whose ignorance and prejudices they live do not want to be convinced. It has been their policy not to listen or to learn, and we do not suppose that any decision against them by any tribunal would mitigate their prejudices.

We have, however, a right to hope that for many years to come no Government will be found to yield again to the insensate howling of these people, or—by another unnecessary inquiry—to unsettle the working of these most necessary and beneficial laws. It is a part of the duty of our rulers to protect us against the clamour of those who would break down the laws enacted for our protection, and, in our opinion, the report of this Committee fully justifies future Governments in refusing to be bullied into further inquiries.

DISINFECTION.

ROBERT KOCH has shown by experiment that a one per cent. aqueous solution of carbolic acid had no effect in arresting the development of the permanent spores (Dauersporen) of the splenic bacillus; a 2 per cent. solution weakened the development after three days' action of the supposed germicide; a 3 per cent. solution weakened it after two days' action—the development ceased after seven days; development was weakened in a 4 per cent. solution after twenty-four hours' action—

it ceased after three days; and finally, a 5 per cent. solution weakened the development after twenty-four hours, and arrested it after two days. This result was a totally unexpected one. We are accustomed to look upon a 2 per cent. solution of carbolic acid as capable of destroying the vitality of microscopic germs in a few seconds. The surgeon washes his hands and rinses his instruments in it, and then believes himself to be freed from infectious germs, and to be in a position to handle wounds without danger to his patients. The above experiments show, however, that if by accident the spores of the bacillus anthracis, or of any other infective germs having an equal power of resistance, are on his hands or instruments, and if they are not removed by the mechanical action of the water, the addition of the carbolic acid to the water cannot have been of the slightest use in protecting the patient from infection. On the other hand, however, carbolic acid showed itself a good destructive agent against the lesser resisting spores of the bacillus anthracis, development of which was arrested by a 0.5 per cent. solution in a few minutes. Carbolic acid in the form of vapour was shown to be quite inert at ordinary temperatures, but more active at higher. The same was shown to be the case with sulphide of carbon. Oily and alcoholic solutions were completely useless, both in the case of bacillus anthracis, and in those of the more easily destroyed bacilli. All the raw products containing carbolic acid were inferior to the acid itself as disinfecting agents, tar and coal-tar being quite inert. Sulphurous acid produced by the burning of sulphur showed itself quite powerless against material containing spores. Bacilli and micrococci contained in disinfection chests were destroyed in twenty minutes, but when treated in rooms little or no effect was produced. The disinfective process was rendered somewhat more energetic by the previous moistening of the articles.

Chloride of zinc, of which it has been said that a 1 per cent. solution is a certain disinfectant, was found, in a 1 per cent. solution, to be capable of weakening the development of the micrococcus prodigiousus only after sixteen hours' action; and even after forty-eight hours it failed to completely arrest it. Against anthrax spores a 5 per cent. solution was absolutely without effect after thirty days' action. Of other substances, bacilli spores were destroyed within one day by freshly prepared chlorine water, by a 2 per cent. solution of bromine water, iodine water, a 1 per cent. solution of corrosive sublimate, a 5 per cent. solution of hypermanganate of potash, and a 1 per cent. solution of osmic acid, by formic acid within four days, by a 5 per cent. solution of chloride of lime, sulphide of ammonium, by a 5 per cent. solution of ferric chloride, by a 5 per cent. solution of picric chloride within six days, by a 1 per cent. solution of arsenic, by a 1 per cent. solution of quinine with hydrochloric acid, by a 2 per cent. solution of the latter within ten days, and by ether within thirty days. The following were shown to be absolutely or nearly without effect on the spores of anthrax:—Distilled water, alcohol, glycerine, oil, sulphide of carbon, chloroform, benzol, petroleum, ether, sal. ammoniac, concentrated solution of chloride of sodium,

bromide of potassium, iodide of potassium, 1 per cent. solution of sulphuric acid, 5 per cent. solution of the sulphates of zinc and copper, alum, sulphate of alumina, 1 per cent. permanganate of potash, 1 per cent. chromic acid, 5 per cent. chromate and bichromate of potash, 5 per cent. chlorate of potash, 5 per cent. boracic acid, 5 per cent. acetic acid, 5 per cent. tannin, 5 per cent. benzoic acid and benzoate of soda, indol, skatol, leucin ($1\frac{1}{2}$ per cent.), quinine (2 per cent.; in water, 40, alcohol, 60), iodine (1 per cent. in alcohol), thymol (5 per cent. in alcohol), salicylic acid (5 per cent. in alcohol; 2 per cent. in oil).

Amongst the substances whose efficiency in arresting the development of spores was tested, corrosive sublimate took the highest rank. In the proportion of 1 : 1,600,000 it delayed the development of anthrax bacilli from spores, and diluted to 1 in 330,000, the development was arrested. Mustard oil—1 : 330,000, delayed the development; 1 : 33,000, arrested it; arseniate of potash, 1 : 100,000, delayed; 1 : 10,000, arrested; thymol, 1 : 80,000, delayed; oil of turpentine, 1 : 75,000, delayed; prussic acid, 1 : 40,000, hindered; 1 : 8,000, arrested; chromic acid, 1 : 10,000, delayed; 1 : 5,000, arrested; picric acid, 1 : 10,000, delayed; 1 : 5,000, did not arrest; iodine, 1 : 5,000, delayed; salicylic acid, 1 : 3,300, delayed; 1 : 1,500, arrested; hypermanganate of potash, 1 : 3,000, delayed; hydrochloric acid, 1 : 2,500, delayed; 1 : 1,700, arrested; camphor, 1 : 2,500, delayed; eucalyptus oil, 1 : 2,500, delayed; benzoic acid, 1 : 2,000, delayed; borax, 1 : 2,000, delayed; 1 : 700, arrested; boracic acid and carbolic acid, 1 : 1,250, delayed; and 1 : 800, arrested.

As in practical disinfection the aim is the destruction of the micro-organisms in the shortest possible time, and not alone the arrest of this development (antiseptis), according to the above results only the following come into consideration:—Corrosive sublimate, chlorine, bromine, and iodine, as 5 per cent. solutions of permanganate of potash and osmic acid must be excluded for practical reasons. Further research showed that bromine in vapour took precedence of chlorine, and still more of iodine, in rapidity of action. Herein corrosive sublimate shows itself only superior to the nitric and sulphuric oxides of mercury.

As regards the use of these substances for closed rooms, bromine, and perhaps chlorine, in vapour may be employed. For the disinfection of transportable objects (linen, beds) the author recommends moist heat. For a thick class of objects that are too large to be disinfected by heat or in closed rooms—railway carriages, and holds of ships, for instance—a 1 per cent. solution of corrosive sublimate should be employed. With this degree of concentration one moistening is sufficient. When the length of time employed in disinfecting is indifferent, then in the latter instance the use of sulphate or nitric oxide of mercury may be considered. Experiments made on guinea-pigs infected with anthrax with the object of testing the power of corrosive sublimate to control the development of the disease, gave only negative results; but the author, nevertheless, does not give up the hope of being able to materially weaken the disease in animals already infected, or even to completely arrest it.

Notes on Current Topics.

Ovariectomy in General Hospitals.

THERE is a wide difference of opinion amongst specialists on the propriety of performing ovariectomy in provincial general hospitals, the objections mainly consisting of general ones, such as the want of special practical skill, experience on the part of the operator, and the difficulty of carrying out all the minute details which are said to so much affect recovery in this special class of cases. Some specialists, whom we need not name, advise that all such cases should be operated on by specialists. The profession attached to provincial hospitals will not agree with this dogmatic opinion; they fairly claim the right to operate in all cases brought under their care; still more, they can adduce facts to support the position, that the results obtained in provincial hospitals can compare with those obtained by some of the best specialists. The following experiences from a moderate-size provincial general hospital will justify the action taken by provincial surgeons. During ten years at the Halifax Infirmary, twelve cases of ovarian tumour have been operated on by the different surgeons attached to the institution. The cases were not specially selected, the ages were various, the pedicles were treated in different ways. All the cases recovered. The conclusion may fairly be drawn that ovariectomy is a standard and accredited operation for all general hospitals where surgeons are apace with the general surgical knowledge of the day, and that the risks are no greater than those encountered in any other severe surgical operation.

Wine Adulteration.

SOPHISTICATION appears to be on the increase, and articles of daily consumption are imitated and adulterated to quite an alarming extent. We lately commented on the dishonest fabrication of French brandy, and we now learn from a report just published that for the last two years the quantity of wine imported into France, and principally from Spain and Italy, has been nearly three times that of the exports. But it is not only from foreign States, but by the fabrication of wine from dried raisins, and a new system of producing a second and third quality of wine from the skins of the grapes that merchants and growers seek to make up for the deficient yield of the vineyards of France. It is estimated that, 2,300,000 hectolitres of wine are now annually made from dried raisins. The mode in which sophistication is carried out is by crushing the raisins and steeping them in warm water. This is left to ferment for a certain number of days, when a white wine is produced with an alcoholic strength of from seven to nine degrees. It is also estimated that $2\frac{1}{2}$ million hectolitres of an inferior kind of wine were last year made from the skins of grapes. This sophistication is conducted as follows:—After the wine is drawn from the grapes, a quantity of water, equal to the volume of wine run off, is poured on the skins before they are put under the press. To every twenty-two gallons of water thirty-five pounds of sugar is added, together with a little tartaric acid. It is then set aside for fermentation, and in about ten or twelve days the liquor will have attained to ten or twelve degrees of strength of

alcohol. By these and other means, some 95 or 100 million additional gallons of a certain kind of wine is produced for mixing, blending and adulterating. In this way the wine production of France in 1881, which was said to be a very poor year, was artificially brought up to 38,590,000 hectolitres, or 849,353,000 gallons.

The Indian Contingent for Egypt in 1800.

THE total strength of the force was about 5,200 fighting men, of which 2,800 were King's troops, 450 East India Company's artillery, and 1,950 native troops. The march of this force from Cosseir to the Nile at Kinneh was a very trying one, the heat being intense and water very scarce. At two out of the seven halting-places there was none at all, the men who had been sent on in advance to dig wells not having been able to find any. [This, no doubt, would have been otherwise had Abyssinian pumps been invented then, and supplied to the force.] The marching was all done at night. Provisions were carried, cooked in advance at the depôts that had been constructed along the road. [There was no opposing enemy *en route*.] Two gallons of water per head were taken on camels for the marches where no water could be procured, and this allowance was eked out with wine. [Madeira and claret were the wines usually drank in India at the date referred to.] Where water was procurable, the men had an allowance of spirits in lieu of wine. Thanks to the excellence of the arrangements, the march was executed with hardly any loss. [What better results could happen even in the present days of so-called *scientific* sanitation?] The contingent remained in Egypt upwards of a year. On the return journey it marched across the desert from Cairo to Suez. This march was performed in five days, and with the loss of only three men.

Arsenic in Wall Papers.

WE have received from Messrs. Woollams and Co., manufacturing paper-stainers, a communication respecting the "Portable Box for Testing Arsenic," of which we recently gave a description in these pages. Messrs. Woollams and Co. contend that without microscopical verification of the crystals of arsenious acid to be obtained from the arsenic deposited on the copper in Reinsch's test, it is impossible to determine the exact nature of the matter so deposited. In the directions for using the apparatus recently noticed, it is assumed that the deposition of a substance on the copper is ample evidence that arsenic is present in the solution under examination, although it is suggested that confirmation of the suspicion should be obtained through further examination by a skilled analyst. On this point our correspondents observe:—"We have good cause to know that people using this test are not likely to have such papers tested by a 'competent chemist.' We have unfortunately on several occasions had difficulty in combating false reports made by experts who have unjustly condemned our papers, through reliance upon this test without carrying it to its ultimate end. Unless well-defined crystals of the proper shape are obtained, it is useless and unmistakably calculated, in the present state of the manufacture, to do more harm than good. We ourselves constantly make use of a test, simple in character, and much more reliable in its

results than the one referred to above; but it is not sure enough in unskilled hands to justify us in directing public attention to it, and we greatly regret that it is not within our power to suggest any process that can safely be recommended to take the place of the one we condemn. A test that would *unerringly* determine the absence of arsenic in presence of other matters giving somewhat similar chemical reactions would be a real boon to manufacturers. In the present state of public knowledge of this subject, it appears to us only too clear that any attempt to deal with it without the aid of professional experts can only add to rather than diminish the existing uneasiness and confusion."

London Water Supply.

MESSRS. CROOKS, ODLING, AND TIDY present a favourable report on the water supplied to London during the month of July last. They observe that, despite the storms so frequent during the month, the general degree of freedom from turbidity of the water, though less complete than that which was noticeable throughout the two preceding months, was, on the whole, very satisfactory; while in respect of colour, aëration, and freedom from excess of organic matter, the previous excellent condition of the water was fully maintained. In the case of water supplied by three companies only was any fault found with its appearance; three samples of the East London Company were found "very slightly turbid," and one "slightly turbid," out of the twenty-six samples. The West Middlesex and the Lambeth Companies were the others which supplied water slightly turbid on one or two occasions. The general average supply of water was thus of good quality and condition, and bears very favourable comparison with the most satisfactory periods.

General Hospitals and Infectious Diseases.

SOME time ago we gave an account of an incident which occurred at Guy's Hospital, whence a man suffering from small-pox was sent, without any means being taken to protect the public, to the Stockwell Small-pox Hospital. The matter having been brought before the Metropolitan Asylums Board, correspondence subsequently ensued between the Guy's Hospital authorities and the Local Government Board. It was explained that the rules of the hospital prohibited the admission of any persons suffering from small-pox or scarlet fever, and in those cases where the disease developed after admission, such patients were at once discharged either to an appropriate institution or to their own homes. The governors urged the necessity that the regulations which prevented the admission of general hospital cases to the hospitals under the Asylums Board should be removed, so that on the certificate of the resident medical officer a transfer might be arranged without further trouble. All the suggestions having been considered by the Stockwell Hospitals Committee of the Board, they reported that it is highly desirable that every general hospital should possess a room for the temporary isolation of infectious cases, pending removal in a proper ambulance to a special institution, and that such removal should be authorised by the resident medical officer at the hospital. The Board decided to forward a communication to this effect to the

Local Government Board and to every general hospital in the metropolis.

Royal Free Hospital.

THE fifty-fourth annual report of the Royal Free Hospital, Gray's Inn Road, is a satisfactory document, and shows the institution to be in a condition which enables it to continue to confer its advantages on the populous districts whence patients flock to it. The hospital has good reason to congratulate itself on the amount of support accorded to it during last year, and the committee are apparently alive to the fact that its income has undergone less diminution than might have been looked for. The total receipts in the twelve months from all sources amounted to £11,486 19s. 2d., thus being over £4,000 less than the amount obtained in 1880. The principal falling off, however, is in the matter of legacies—never a reliable source of income. The number of in-patients treated was 1,616, and 21,362 out-patients received attention and medicine. By a regulation adopted in 1879, the number of new cases seen in the out-patients' department is limited to 55, and this plan is said to work in a most satisfactory manner. The medical officers are not overtaxed, and no really urgent case, it is said, is ever sent away. There are 22 students attending the hospital from the London School of Medicine for Women, and it is found that the association with this institution works admirably. During the year certain changes in the staff of the hospital have taken place, Mr. J. G. Mackinlay replacing Mr. J. A. Critchett as ophthalmic surgeon, and Dr. E. B. Baxter in place of Dr. W. A. Sturge as physician.

Heterodoxy gone Mad.

A GERMAN doctor, one Hamerink, of Prague, has written a book which some one has thought worthy of translation into English. The author is evidently not troubled with doubt. Vaccination is denounced by him as worse than useless, without the reader being favoured with the evidence leading to that conclusion. He is told cow pox has no connection whatever with small pox, and that "in the event of an attack of small pox it is of no manner of importance whether the patient is vaccinated or not." Though he may find this difficult to reconcile with a statement on the opposite page that "persons are most liable to be attacked by small pox in the years immediately succeeding vaccination." Vaccinators with original cow pox lymph are described as "for the most part charlatans, who produce the pustulation in the udder of the calf or cow by solutions or ointment of tartar emetic, and drive a fraudulent trade in it." All aperients are said to be superfluous and mischievous, and Hunyadi-Janos water is specially singled out for condemnation, apparently because of its dissimilarity to ordinary drinking water. "Disinfection does nothing in the way of preventing disease or rendering it milder." And so on, *usque ad nauseam*.

It is proposed to celebrate the centenary of the Hull Infirmary, with the object of enlarging, improving, and endowing the institution, and of obtaining the addition of a convalescent home in connection with it.

The Irish Pharmaceutical Society.

A VERY serious breach of continuity in the Council of this Society has taken place. At its last meeting there were two candidates for an Examinership in Practical Pharmacy—a metropolitan and a provincialist. On a division the metropolitan was elected, whereupon two members, Mr. Payne and Dr. Whittaker, handed in their resignations, and Mr. Pring intimated that he would do the same.

The Dublin Schools of Medicine.

THE reconstruction of the School of the Irish College of Surgeons which, it will be recollected, was the subject of a serious contest amongst the Fellows of the College last June, is now in a forward state. The works, which are to cost £3,000, include the lowering of the floor and windows of the dissecting-room, the erection above it of a large physiological laboratory, the construction of a "bone-room," in which the students may work at their myology and osteology from marked and mounted specimens, the erection of new preparation-rooms, and other offices needful for carrying on the school work, and lastly, the reconstruction of the lecture theatres. All these works are pressing forward to completion, and, as the chemical laboratories were recast last year, the school, when it opens next October, will be very complete. The Carmichael School was new a couple of years ago, and, at the time of its building, the School of the University of Dublin underwent extensive alterations to fit it for modern methods of teaching. The Board of the Ledwich School of Medicine and Surgery have also determined to make certain alterations and additions at their institution, so as to constitute it thoroughly efficient in every respect. Contracts have been signed and the work is now being rapidly carried on, the estimated cost being upwards of £500. It will include a physiological laboratory, a chemical laboratory capable of accommodating at least seventy students, a museum for the teaching of pathology and osteology, a lavatory supplied with hot water, spirit tanks for subjects, &c.

The Pharmaceutical Conference Meeting.

YESTERDAY the nineteenth annual meeting of the British Pharmaceutical Conference commenced in Southampton. The sittings are held in the Watts Memorial Hall, commencing at 10.30 a.m. each day. At 1 p.m. on each day there will be an adjournment until 2.30 p.m., for the purpose of luncheon, and the business proceedings terminate about 5 p.m. to-day (Wednesday). On Thursday the visitors are invited by the members of the local committee to accompany them upon an excursion to the Isle of Wight, visiting Ryde, Ventnor, Brading, and the Landslip.

THE scarlet fever epidemic at Accrington is increasing. It has been decided to close all the schools of the town.

A MIDWIFE in Prussia having washed the body of a person who had died of typhus, and carried the infection thence to a lying-in woman, the Prussian Government, under order of June 26th, 1882, has forbidden the laying out of corpses by midwives, under a penalty of 10s., or in default three days' detention.

Sudden Deaths of Medical Men.

WE regret to announce the sudden death of Dr. William Middleton, sen., of Mullingar, which melancholy event occurred in the afternoon of Wednesday last, at his residence in that town. At an inquest held Mr. C. Sixsmith deposed that he was an apprentice to the late Dr. Middleton, and resided in the house with him; on Wednesday deceased appeared in his usual good health; was not present at his death. Anne Buckley deposed that she called at Dr. Middleton's establishment for some medicine; the doctor was sitting behind the counter in the shop; he gave her the medicine, and when he turned to get her change he put his hand on his breast and complained of a great pain there, and the words were hardly spoken when he fell behind the counter; witness alarmed the servants and they came to her assistance, and helped witness to carry deceased out to the front of the shop; Mrs. Middleton also assisted; deceased died in about two minutes after. Dr. W. Middleton, nephew of deceased, deposed that he was of opinion that death occurred from heart disease. There being no further evidence, the jury returned a verdict that "deceased died from heart disease."

Dr. Kinane, Templemore, while on a visit at the house of sister-in-law, at Bansha, died suddenly last week. Deceased drove, on Thursday, from Clonmel to Bansha. He complained about 11 o'clock, when retiring to bed, and died at one in the morning. A particularly distressing feature of the sad occurrence arises from the fact that his recent marriage was announced in the papers. Deceased enjoyed a large and respectable practice.

Early on Friday morning week Dr. William White died rather suddenly at his residence, Borris Castle, Queen's County. The doctor had been in delicate health for some months past. In the year 1879 he was superannuated as the medical officer of Donaghmore union, the duties of which office he discharged for many years with rare ability. He was about 73 years of age, and his death has cast a gloom over a large circle of friends, to whom his many excellent qualities and abilities as a medical man had endeared him.

An F.R.C.S. Eng. Protection Society.

A MEETING of Fellows of the Royal College of Surgeons of England, called by advertisement, was held at the Medical Library, Worcester, on Thursday, August 10th, President C. G. Wheelhouse, Leeds, in the chair. There were present thirty Fellows, most of them occupying leading positions in the provinces. Mr. Bartleet said he had received numerous letters approving of the meeting at Worcester, and expressions of regret at inability to attend from Mr. Macnamara, London, and Mr. Pilcher, Boston. Mr. Wheelhouse and Mr. Bartleet having explained the objects of the meeting, it was proposed by Mr. Lawson Tait, seconded by Mr. Oliver Pemberton, and after considerable discussion, resolved *nem con.*, "That an Association of Fellows of the Royal College of Surgeons of England be and hereby is formed." "That the objects of this Association be the consideration of all matters affecting the interests of the Fellows and the government of the College." "That the annual meeting of this Association be held at, and during, the annual meeting of

the British Medical Association." "That the Fellows attending the present meeting do form a Committee of this Association for the present year, and that Mr. Wheelhouse be President, Mr. Husband Treasurer, and Mr. Pearce Gould and Mr. Bartleet Secretaries, and that all Fellows of the College be eligible as members upon payment of an annual subscription of five shillings."

Compensation for Impure Water Supply.

THE Corporation of Huddersfield is in process of illustrating the false economy and health risks of a badly fitted water supply. They went to great expense in providing pure water for the citizens, but caused and allowed the connections between their mains and the houses to be made by a lead service pipe. This pipe conveyed not only the water, but also a dose of dissolved lead into the house of a solicitor, who, after a long course of unexplained preliminary symptoms, suffered from colic, wrist drop, and other marked symptoms of saturnine poisoning. The Corporation does not seem to have seriously denied that the water, as it reached the house, was poisoned, but pleaded that their duty and responsibility ceased when they brought the liquid pure into the mains. The solicitor, however, insists that they, having made the house connections, were liable for defects in them. This question remains for settlement before a superior court, but, meanwhile, the jury has assessed damages at £2,000 in case the plaintiff gains a judgment on the point of law.

A New Licensing Body.

In the House of Commons, on the 8th inst., the Vice-President of the Council was asked whether it was intended "to place the Victoria University, Manchester, without delay, on the same footing as the older Universities with regard to the granting of medical degrees," in accordance with the recommendation of the Royal Commissioners on the Medical Acts. In reply, Mr. Mundella stated that he understood that an application was about to be made to Her Majesty in Council for a supplemental charter to enable the Victoria University to grant medical degrees, and that the initiatory steps would be taken at the usual meeting of the Court of Governors in November. When the petition is received it will be submitted to the Queen at the next ensuing Council.

Abortion (?) or Unqualified Assistants.

THE Medical Officer of Health for the City of Bristol, in his report for the quarter ending June last, calls attention to the number of uncertified causes of death registered within his sanitary district. It appears that during the three months under notice thirty-three uncertified causes of death were registered in Bristol, equal to 3.1 per cent. of the total deaths. Nineteen of these thirty-three deaths were attributed to premature birth; and Mr. David Davies records his opinion that a record of the primary cause of the premature birth should in such cases be ascertained and recorded.

THE Companionship of the Order of the Bath has been conferred on Fleet Surgeon Doyle Money Shaw, Royal Navy.

A LARGE number of cases of insolatio at New York are reported, resulting from the intense heat of the last few weeks.

PROFESSOR GERHARDT, of Würzburg, is to succeed Friedrich, in Heidelberg, and Professor Rossbach Nothnagel, in Jena.

MR. RICHARD AXFORD, late medical officer for the workhouse and third district of the Bridgwater Union, has received a superannuation allowance of £25 a year.

A WOMAN in America suffering from melancholia not long ago passed three tea-spoons per anum. Amongst the symptoms observed during her attempt to digest them were abdominal pains, vomiting, and peritoneal irritation.

M. SAINT PAUL has offered the French Academy of Medicine a sum of 25,000 francs to found a prize for the discovery of a cure for diphtheria. The competition is open to all the world, and not confined to the medical profession.

We are greatly surprised to observe that Dr. Cameron, M.P., was amongst the minority of the Select Committee on the Contagious Diseases Acts who went for a repeal of these laws. The learned member's presence in such company is, truly, one of those things that nobody can understand.

On the 1st of September an Obstetrical "Operations Institut" is to be opened in Vienna, with the object of affording facilities for the advanced instruction of a larger number of obstetricians. It will be under the superintendence of three professors of obstetrics of the University of Vienna, and will be open to all Austrian doctors in medicine.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Halifax 11; Derby 13; Edinburgh, Plymouth 15; Bristol, Wolverhampton 18; London, Preston 19; Portsmouth, Norwich 20; Glasgow, Brighton, Leeds, Cardiff, Birkenhead, Sheffield 21; Oldham, Birmingham 22; Dublin, Liverpool, Manchester 23; Leicester, Salford 24; Blackburn, Nottingham, Bradford 25; Hull, 26; Huddersfield 27; Newcastle-on-Tyne, 28; Bolton, 29; Sunderland 31.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 21, Bombay 20, Madras 28; Paris 21; Geneva 16; Brussels 24; Amsterdam 22; Rotterdam 16, The Hague 24; Copenhagen 23; Stockholm 29; Christiania 20; St. Petersburg 48; Berlin 41; Hamburg 26; Dresden 29, Breslau 37, Munich 23, Vienna 25, Prague 25, Budapesth, 37, Trieste 37, Rome 24, Turin 24, Venice 35, New York 40, Brooklyn 39, Philadelphia 28, and Baltimore 33.

THE annual death-rate per 1,000 from diarrhoea in the large towns last week averaged 2.7, and showed a further increase upon that recorded in recent weeks. The rate

from this disease in the several towns last week ranged upwards from 0.6 in Birkenhead, and 0.7 in Wolverhampton and Halifax, to 6.8 in Bolton, and 9.9 in Leicester. The highest annual rates from scarlet fever were 2.0 in Hull, and 2.2 in Sunderland; from measles, 6.3 in Huddersfield, and 1.0 in Hull and Brighton; from whooping-cough, 2.6 in Sunderland and 1.6 in Preston; and from "fever," 1.8 in Birkenhead and 1.3 in Derby. Small-pox caused 4 deaths in London and its suburban districts, 3 in Newcastle-upon-Tyne, and 1 in Nottingham.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DEATH-RATE OF GLASGOW.—For the week ending with Saturday, the 12th inst., the death-rate of Glasgow was 21 per 1,000 per annum of the population, being a slight decrease compared with the preceding week, when the deaths registered equalled 24 per 1,000. For the corresponding periods of 1881, 1880, and 1879, a rate of 21, 23, and 17 respectively was registered.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 12th inst., the mortality in Edinburgh was 66, and the death-rate 15 per 1,000. There were 15 deaths under 1 year, and 12 above 60, of which 4 were above 80, and 1 above 90 years. Diseases of the chest accounted for at least 30 deaths, and zymotic causes for 1—a case of whooping-cough in the New Town.

FEVER EPIDEMIC AT COUPAR.—Considerable alarm was created in this town by the recent publication by Dr. William Whitelaw, Medical Officer of Health, with special reference to the prevalence of fever in Coupar and district. Despite the utmost precautions to prevent the spread of the infection, it is apparent that the disease still lingers in a dangerous form in the district. Dr. Whitelaw reports that since the date of his last report, on the 9th inst., other three cases have been noted, and that two cases previously reported have proved fatal. Two more cases cause great anxiety, but all the others are doing well. The disease has not yet spread to other than the infected district.

THE REGISTRAR-GENERAL'S RETURN.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, August 12th, states:—The death-rate was 20.1 per 1,000 of estimated population. This rate is 1.2 above that for the corresponding week of last year, but 1.2 below that for the previous week of the present year. The lowest mortality was recorded in Edinburgh—viz., 15.9 per 1,000; and the highest in Aberdeen—viz., 22.3 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 5.0 per 1,000, or 0.2 above the rate for the previous week. As usual at this season, there was a considerable number of deaths from diarrhoea and other bowel complaints, these deaths being most frequent in Glasgow, Edinburgh, and Dundee. The other zymotic diseases were comparatively in abeyance. Acute diseases of the chest caused 71 deaths, or three less than the number registered during the previous week. The mean temperature was 61.4, being 2.8 above that of the week immediately preceding, and 5.1 above that of the corresponding week of 1881.

FRASERBURGH.—OUTBREAK OF MEASLES AMONG FISHERMEN.—An outbreak of measles has occurred among the Highland fishermen at present at this town, and in consequence of the sudden death of five of their number they are

in a state of great excitement and alarm. For some weeks it has been known that many cases of measles were occurring among them in some quarters, as many as ten or twelve being ill in one house at a time. On the 12th inst., in a house where nine lodged together, three women died within a few hours of each other, and three days afterwards another succumbed, while a fifth is dangerously ill. In another part of the town a death occurred from the same disease on the 12th. The medical gentleman in attendance on the women states without hesitation that the deaths resulted from measles, and that no unusual symptoms were present beyond what the crowded and confined condition of the patients' houses would naturally produce.

Literary Notes and Gossip.

WE notice that the articles "On Climate in Relation to Organic Nature," which appeared in our columns some few months since, from the pen of Surgeon-General Gordon, C.B., have been reprinted in book form, and circulated by the Philosophical Society of Great Britain.

DR. CUSHING, of New York, forwards us a pamphlet, in which the compression of the carotids as a remedial measure in epilepsy and maniacal excitement receives a careful discussion. He has devised two instruments for effecting the purpose more readily than by the fingers, and narrates several illustrative cases.

AN important literary and scientific discovery is announced from Salonica. The works of Galen, which were supposed to be lost, have been discovered by M. Papageorges. They are in manuscript; date from the fifteenth century, and appear to have originally formed 248 sheets; 144 are in good condition, 24 are mutilated or worm-eaten, and 80 are missing.

WE understand that there is every prospect that the *Dictionary of Medicine*, which has been several years in preparation, will be issued during the coming publishing season by Messrs. Longmans, Green and Co. It will form a volume of over 1,800 pages, and be the most complete work of the kind ever issued, and will altogether supplant the now obsolete work of Copland.

BRAITHWAITE'S RETROSPECT for the first half of 1882 quite maintains its excellence as a *résumé* of the advances and improvements made since the end of last year. The present volume is the *eighty-fifth*, and there is good reason to hope that the work may long continue to be the able and invaluable guide to the past that it has become. Not a few persons would be almost at a total loss how to proceed without the help the "Retrospect" renders.

THE Chair of Natural History in the University of St. Andrews, recently vacated by Professor H. Alleyne Nicholson, on his appointment to lecture on Natural History at Aberdeen, has been conferred on Dr. Mackintosh, Superintendent of Murthly Asylum, Perthshire. Dr. Mackintosh is familiarly known to the scientific world as an original observer, and has sufficiently established a claim to the position he now occupies. The patron of the chair is the Marquis of Ailsa.

MR. GREENWOOD, a member of the medical profession, who has since been admitted to the legal profession as a barrister, has just published a work on "The Laws Relating to Medical Men," which is likely to be in considerable request, as there are no modern works except cumbersome tomes to consult in any passing difficulty. Mr. Greenwood has now supplied this deficiency with a small five-shilling volume, and although there are one or two suggestions we shall hereafter make in view of a second edition, the compilation is on the whole exact.

FRANKFORT was the scene last week of the annual congress of German anthropologists. The presidential address was devoted to a record of the development of anthropology

during the last ten years, and one of the most interesting papers communicated subsequently was one by Dr. Schlie-mann on his most recent discoveries at Troy. Virchow contributed a lecture on the work achieved by the late Charles Darwin in the field of anthropology, and paid a high tribute to the deceased naturalist's all-embracing knowledge. The Congress has been very successful, and was attended by over 500 members of the Anthropological Association.

DR. NATHAN BOZEMAN, of New York, has reprinted in the form of a pamphlet his paper on "Genital Renovation," contributed to Vol. VI. of the "American Gynecological Transactions." This work deals with the operations of Kolpostenotomy and Kolpoekpétasis, by which Dr. Bozeman has succeeded in curing a number of patients suffering from fistulae of various kinds and involving the urinary or genital passages. It will be found of high interest and value to every gynecologist, and will well repay careful perusal, even by those who may not, as probably many in this country will not, wholly endorse the views of its author.

L'Année Médicale (fourth year), edited by Bourneville, is a *résumé* of the progress of medical science during 1881. It is divided into sections of anatomy, physiology, medicine (including medical jurisprudence), surgery, obstetrics, therapeutics, and hygiene. It gives an epitome of the best papers that have appeared during the year in those departments. In comparatively small bulk, the volume is wonderfully exhaustive, and we notice that considerable prominence is given to British and American literature. It accomplishes in an admirable manner its objects, and we cordially commend *L'Année Médicale* to the busy practitioner and student wishing to learn what has been the year's work among our neighbours.

THAT much desired detail—the size of some one molecule—is at last forthcoming, and now, maybe, the souls of physicists will sleep in peace, or gloat over the possibilities of calculation opened up by the newest sensation in the way of figures. After we know not how many years of calculation, Dr. Heen, taking as the basis of his performance the phenomena of capillary attraction, has discovered that a molecule of water measures in diameter $75 \cdot 10^{-9}$ mm. = 0·000,000,075 millimetre. From this it is a comparatively easy matter to find the number of molecules in an ordinary drop of water, which, taking it as measuring a cubic millimetre (1·6 minim), would contain just *twenty-five trillions* of molecules. We need not, therefore, be astonished at the magnifying power that even bacilli require for their revelation.

THE publication of Sir Henry Thompson's "Diseases of the Urinary Organs" in a cheap form, to which we referred in our last issue, has been seized by one or two correspondents to this and other medical journals as a pretext for the demand for cheap medical literature. They complain of the costliness of medical as compared with other works, and of the poverty of the majority of the profession combined, as precluding the possibility of their purchase. This is one side of the question, and the facts cannot be disputed, but deplored. There are, however, other points which force themselves irresistibly to the notice of all whose experience has brought them face to face with the cost of production, as a set-off against the demand for cheapness. True, Sir Henry Thompson has reduced his half-a-guinea book to half-a-crown, but then Sir Henry Thompson would hardly be placed in the category of "poor authors," and an actual loss upon the sale of his work would probably not deter him issuing the next edition at even a lower price, or announcing that "members of the profession could obtain copies gratuitously on presentation of their cards." But this is an exceptional case, and in dealing with the subject as a whole we must take the ordinary author and publisher into consideration.

WE will take first the author who has, or thinks he has, something to write about, and who wishes to bring out a book. If he be an honourable man, and takes into consideration his chances of sale among the profession alone, he is met with the fact that he has but a small constituency to appeal to, and that on an average not more than one in fifty can be expected to purchase his work. Should illustrations be required, their expense is extremely heavy, and must be

provided for. He takes his work to a publisher, who, if he be unknown as an author, will probably decline to issue the work except at the author's risk. The latter cannot afford to publish with the prospect of a heavy loss, and thus perforce a moderately high price is placed upon the book in order to meet a probable deficiency. On the other hand, we will suppose the publisher to issue the work at his own risk; he has to take the same objective chances into consideration—the cost of advertising, and the knowledge that the very large majority of medical works do not pay the cost of production. He lives by the profit on the sale of these works, and he calculates logically that the sale of 500 copies of a book at five shillings will pay him a larger profit in proportion than 1,000 copies at two shillings; and that the sale of 2,000 copies at one shilling will result in actual loss. Can we wonder at the course he elects to follow? The matter is different with general literature, where the masses are considered, or with school books, where issues of 100,000 copies are not uncommon, and successive editions are printed from stereotyped plates. There is no scope for this in medical literature, and we therefore cannot anticipate a change.

* *

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, July 26th:—*The Laws Relating to Medical Men*, by James Greenwood, barrister, and L. S. Forbes Winslow, M.R.C.P. Lond. Therapeutical Remembrancer, by J. Mayne, M.D. (2nd edition). Reports of the Metropolitan Asylums Board for the Deptford and Fulham Hospitals. Proceedings of the Liverpool Medical Institution, Vol. III. *The Chemistry of Foods*, by A. Wynter Blyth, M.R.C.S. A Manual of Gynaecology, by Drs. Hart and Barbour. Hospitals: their History, Construction, and Hygiene, by J. F. Sutherland, M.D. The Army Medical Report for 1880. Remarks on Climate in Regard to Organic Nature, by Surgeon-General Gordon, M.D., C.B.

IRISH POOR-LAW SUPERANNUATION.

THE sittings of the Select Committee on this Bill were suspended on Saturday week, it being obviously hopeless to pass the Bill this session. It was, therefore, resolved to report the evidence to the House of Commons, with an official statement that the Government and Irish Local Government accepted the principle of the amendments to the Bill put forward by Mr. Meldon, M.P., on behalf of the Irish Medical Association and Union Officers' Association. This decision pledges the Government to support *compulsory* superannuation at the Civil Service rate of pension, and we entertain a sanguine hope that the Bill will become law early in next session. The evidence is in print, but we are obliged to refrain from publishing it until it is presented to Parliament.

Correspondence.

MIDWIVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leader in your issue for August 9th and Dr. Peirson's letter in same bring to my memory the thought that I had intended in July, at your provocation, to publish my experiences of this branch of professional questions, but a family bereavement and professional demands upon my time prevented me doing so till now.

There lived in this neighbourhood until some sixteen years ago an old lady whose boast it was that she had attended in her time almost all the child-bearing women (some 200 or 300) in her parish. Many of those she had attended in at least six or seven *accouchements*, and some of them she enumerated as having been "brought into the world" themselves by her "and their mothers before them." She claimed to have received proper professional training from

a male *accoucheur*, and this appears to have been a reasonable claim, for her services were often sought to give an enema, or to pass the catheter upon a male.

Casting up her professional career, she might be called a "lucky woman," as well as a "handy" or wise one, as the mortality in her cases for a period of thirty years was almost nil. Once, some thirty years ago, she had a case of inverted uterus, but possessing more knowledge or more fear than the person who, under similar circumstances, took a knife and cut off the strange or "foreign" body, a young Scotch doctor from a neighbouring town was brought, and he replaced the organ. The woman who happened to meet with this accident, in her second and last confinement, still lives, but the "Scotch doctor" is some years defunct. The narration of the above history brings to my mind the memory of some similar accidents. Some years ago there came to reside in the old midwife's hamlet a male *accoucheur*, and he was so expert at using forceps that he had recourse to them in at least a fifth of his cases. And he "aired" or "plumed" himself on his ability in this so much, that he is alleged to have abounded the "instruments" to some working youths, and demonstrated to them how he used them. Once a patient of his on whom the "instruments" were used was so unfortunate as to have an inverted uterus; but she lives not, nor did she live many days after the misfortune.

Within the last week I have heard of a case where the unqualified assistant of a somewhat "big gun" is alleged to have told the mother of a woman whom he had "accouched" that she was a very weak woman, as a piece of her womb had come away in his hand. It is to be hoped the news is not true; but some untoward accident must have occurred, as neither master nor man could succeed in passing the female catheter upon the patient after delivery. In the course of a few days Nature relieved the woman, and the urine came dribbling away. Since that, the woman is reported as progressing, and I hope that news is true.

Such a history as the above proves the need of information among the public, and the need for duly qualified practitioners of all kinds—male and female.

My lowest fee for midwifery is a guinea (in a case of distress, and the parish doctor not available, my fee would be nil); but I will undertake to educate any number of intelligent, respectable women for a fee of two guineas, to practise midwifery, and my action in such an affair is, I consider, honest and professional.

I am, Sir, yours respectfully,

Aug. 16th, 1882.

HOMO.

THE DEBATE ON ALCOHOL IN THE HEALTH SECTION AT WORCESTER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have seen no reference in your esteemed journal to the very remarkable debate on alcohol which took place in the Section of Public Health on the occasion of a paper read by Dr. Norman Kerr in that section a week ago. Dr. Kerr brought forward what seemed to me a most conclusive set of statistics, to prove that in all climates, whether at home or in India or Norway, the longevity of total abstainers from alcoholic drinks was very considerably greater than that of even moderate drinkers of beer, wine, and spirits. No one explained away these facts.

It has often been stated by actuaries that such life offices as make a distinction between policies which are granted to total abstainers and others, find a considerably greater risk in granting insurances to even those who style themselves "moderate drinkers." For instance, the United Kingdom Temperance and General Provident Institution is a life assurance office which insures members in two sections, one in which all are total abstainers, and in the other are "moderate drinkers," all intemperate persons being, of course, excluded. These two sections are exactly alike in every other respect, about 20,000 lives being insured in the General Section, and 10,000 in the Temperance Section. Returns of the expected and actual claims on these sections have been accurately drawn up and published; and from them it appears that from 1866 to 1879 inclusive, in the General Section 3,450 claims were expected, according to the tables of mortality, and 3,444 were actually made. In the Temperance Section, however, 2,002 deaths were expected, but only 1,433 took place; that is to say, the deaths

among the abstainers were 29 per cent. less than among the moderate drinkers. And the quinquennial bonuses in the Temperance Section were $17\frac{1}{2}$ per cent. greater than those given in the General Section.

Under such considerations as these, and similar ones mentioned by Dr. N. Kerr and others in this debate, I am sometimes puzzled when I go out to a dinner where there are many celebrated members of our profession, to see them consuming wine, beer, and spirits pretty nearly as freely as the outside world. Can it be that they are not acquainted with these statistics? I suppose so. It is worth while hearing what anyone has to say in favour of alcohol in their face.

I am, Sir, yours obediently,
London, Aug. 16th, 1882. C. R. DRYSDALE, M.D.

Notices to Correspondents.

65 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

AN AGGRIEVED STUDENT will find the subject referred to in our "Literary Notes and Gossip" column.

JAMES.—The gossip about His Royal Highness is of the customary nonsensical type, and has no foundation in fact.

MR. HY. MOSS.—The conclusion is logical, and the matter must eventually end as you anticipate. Should it result in his determination to stick to the post at all hazards, we will try to help you out of the difficulty on hearing again.

BICYCLE-RIDING AS A CAUSE OF HERNIA.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have at present a patient under my care suffering from inguinal hernia. Presuming his statement that he does not go in for athletics, or lifting weights, to be correct, is it possible that his affliction has been brought about by bicycle-riding, he being an enthusiast in this direction? I shall be glad of the opinion of any of your correspondents with a view to elucidate the question, as I have not before met with a case which could not be explained by other causes.

Yours, &c.,

A PROVINCIAL SURGEON.

VERITAS sends us a letter containing an account of a recent inquest held by Dr. Danford Thomas on a boy who had died within a year of receiving an accident. The medical certificate of death was stopped by the local registrar, and an inquest ordered by the coroner, to whom the facts were communicated. This course is necessary by law, wherever death follows within 566 days of an accident, and the registrar had no option but to lay the facts before the coroner; nor had the latter power to act otherwise than he did in the case. "Veritas" asks how far such inquests are called for, and proceeds to class with them those held in cases of sudden death of old persons and children, which can be readily accounted for. He is hardly right, however, in thus regarding them, for it is only in cases of death from accident that the law insists on a full inquiry. We are quite ready to endorse the view taken by our correspondent that inquests are often held needlessly by borough coroners, and that the *curi sacra fames* is a prime incentive to this course in many instances. He will see, however, that the example cited is scarcely one to the point.

MR. S. DAVIES.—Received, and proof shall be forwarded in due course.

DR. CARTER.—Received. Much obliged for the trouble you have taken.

FAUSTUS.—There is no precedent for such a course.

A DABBLER IN ORIGINAL RESEARCH.—There are several good books. "This's Introduction to Practical Histology" and "Cornil et Ranvier Histology" would best answer your requirements.

SUPERANNUATION.—Medical men should try and bring educated pressure on their representatives. Now is the time.

DR. E. (Sec. Medical Society).—Quite a mistake. What we have done for the Bradford Medico-Chir. Soc. we shall do for you if your papers are of equal interest. We have shown what valuable material may be obtained from provincial societies. If it is lost—well, the fault is not ours.

THE ACADEMIE DE MEDECINE PRIZES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I should feel obliged if you could obtain a list of prizes offered by the French Academy of Medicine, with conditions, for 1883. Dr. Bigelow (Boston, U.S.A.) recently obtained one—£200. It is time one came to this country.

London, Aug. 16th, 1882.

Yours truly,
COMPETITOR.

DOUBTFUL.—You are quite justified in pressing for your fee; the fact of your being absent on your rounds when sent for does not invalidate your claim to the retainer. Your patient should have given you earlier notice, and not waited till the last moment.

DR. H. A. S.—Dr. T. King Chambers is Chairman of the Committee appointed by the Medical Council to inquire into the working of the "Unqualified Assistant System." He will doubtless be glad to receive the information.

MEMBER OF A BRANCH.—It is evident that what you call the provincial agitation has had some effect. The Branch meetings are now acknowledged by the Journal. There is a fairly long report of your annual meetings. The subject was discussed by Committees of Council. It does not alter our position. See reply to Dr. E.

Vacancies.

Dore Union.—Medical Officer. Salary, £70, and £17 as Medical Officer of Health for the same district. Applications to be sent to the Clerk on or before Sept. 5th.

Downpatrick Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board, &c. Applications to the Resident Medical Superintendent by Sept. 1st. (See Advt.)

General Hospital, Birmingham.—Resident Registrar and Pathologist. Salary, £130, with board and residence. Applications must be sent to the House Governor on or before Aug. 31st.

Longford Union, Killashoe Dispensary District.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, Aug. 29th.

Appointments.

ADCOCK, H., M.R.C.S., Medical Officer for the Corby District of the Kettering Union.

CLAYWORTH, C. C., L.R.C.P.Ed., M.R.C.S., Resident Medical Officer to the Sydney Hospital, Australia.

CLOUGH, M. E., L.R.C.P.Ed., M.R.C.S., Medical Officer for the Hambledon District of the Droxford Union.

DAVISON, J. T. R., M.D., C.M.Ed., Senior Resident House Surgeon to the Royal Southern Hospital.

DURDIN, E. C. G., L.R.C.S., L.K.Q.C.P.I., Medical Officer for the Deaford District of the Market Bosworth Union.

MONTGOMERY, J. W., F.C.S., Public Analyst for the County of Westmoreland.

O'CONNOR, B. M.D., M.R.C.P.Lond., Physician to the Hospital for Consumption and Diseases of the Chest, Mount Vernon, Hampstead.

ROE, E. H., M.R.C.S., L.S.A.Lond., Medical Officer for the Cadishead District of the Barton-on-Irwell Union.

SELLARS, W. H. I., M.B. Edin., M.R.C.S., Second Resident House Surgeon to the Royal Southern Hospital, Liverpool.

SPIGNER, R. H. S., B.Sc.Lond., M.B.C.S., L.S.A.Lond., Resident Medical Officer to St. Mary's Hospital.

SPURGIN, T., L.R.C.P.Ed., M.R.C.S., Medical Officer for the Third District of the Ongar Union.

STEVENSON, R. D., M.B., C.M.Glas., Resident Surgeon to the Daylesford Hospital, Australia.

SYMENS, C. G., M.R.C.S., L.S.A.Lond., Medical Officer for the Bedford District of the Hoxne Union.

WEBB, C. F., F.R.C.P.Ed., M.R.C.S., Public Analyst for the Borough of Basingstoke.

Births.

FINZI.—On the 10th inst., at Sutherland Gardens, the wife of Dr. L. M. Finzi, M.R.C.S., L.R.C.P.Lond., of a daughter.

HUTCHINSON.—On the 10th inst., the wife of S. J. Hutchinson, M.R.C.S. &c., of Brook Street, Grosvenor Square, and Broudesbury, N.W., of a son.

PIERREPOINT.—On the 4th inst., at The Common, Kaling, the wife of Dr. E. Pierrepoint, of a daughter.

POLLOCK.—July 1, at Swatow, China, the wife of John Pollock, L.R.C.S.I., of a daughter.

SMITH.—On the 13th inst., at George Street, Hanover Square, the wife of Eustace Smith, M.D., F.R.C.P., of a son.

Marriages.

BREIBANE-WATSON.—On the 10th inst., at the Presbyterian Church, Colebrooke Row, James Brisbane, M.D., of 21 Park Road, Regent's Park, to Mary Jane, eldest daughter of the late William Watson, Esq., of 30 Highbury Hill, N.

HARRIS-SMITH.—On the 8th inst., at Patterdale Church, by the Rev. W. Pattinson, M.A., Vicar, Alfred Harris, M.B. and C.M., of Dalston, son of the late Anthony Harris, of Middlesborough, to Grace Elizabeth, widow of the late C. E. Smith, M.D.

Deaths.

CHAVASSE.—On the 13th inst., at Duchess Road, Edgbaston, Samuel Chavasse, M.R.C.S., late of Newhall Street, Birmingham.

COOK.—On the 2nd inst., at Abercrombie Villas, Hampstead, William Henry Cook, M.D., aged 57.

MIDDLETON.—August 16, at his residence, Mullingar, suddenly, Wm. Middleton, aged 67.

TENNANT.—On the 11th inst. suddenly, at Lambert Road, Brixton, William D. Tennant, M.R.C.S., youngest son of the late Rev. Sanderson Tennant, M.A., of Kensington, aged 32.

SCIENCE AND ART DEPARTMENT.

NORMAL SCHOOL OF SCIENCE AND ROYAL SCHOOL OF MINES, South Kensington and Jernyn Street. The Session 1882-83 will open on October 2nd, 1882. The Prospectus may be obtained from the Registrar, Normal School of Science, South Kensington, S.W.

The Medical Press and Circular.

ON

TEMPERAMENT, IDIOSYNCRASY, AND DIATHESIS IN RELATION TO SURGICAL DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1882.

By JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; Professor of Pathology and Surgery, Royal College of Surgeons, England.

LECTURE VI.—(Concluded).

BUT it is not alone in the scrofulous that we encounter risks in connection with catarrh. Those in whom the tissues have undergone senile degeneration, and those, too, who although not old have become seriously enfeebled by other causes, often show an inability to shake off a catarrhal attack, and a similar result is sometimes brought about under the law of habit, when catarrhal attacks have been exceptionally frequent and severe. Apart from the risk of lapsing into chronic disease catarrhal inflammations are in themselves not unfrequently dangerous to life. Many of the forms of acute bronchitis and pneumonia, and some forms of enteritis, peritonitis, and pleurisy, are distinctly catarrhal in their nature—that is, they result from the exposure of an individual to the ordinary causes of a catarrh—and in many of these the popular expression is verified, "he catches his death of cold." Rheumatic fever very often, as is well known, acknowledges a similar cause; and respecting it and the other acute and dangerous catarrhal inflammations, one general statement is true—that if the patient can only live through the attack it will in due course pass off, and pass off completely, leaving him again in good health. This remarkable facility of spontaneous recovery which is a feature of all catarrhal, or, in other words, of all reflex nervous, inflammations has placed physicians in great

difficulty in coming to any satisfactory condition as to the relative merits of different plans of treatment. I will not say that cases of acute pneumonia, or acute rheumatism, or severe catarrh recover as well under one plan as another. I should be going far out of my province to make any such insinuation, and I should be saying, too, that which with my small amount of information I certainly do not believe. This, however, I must repeat, that there is in each and all of the examples of this type of inflammatory attack a natural tendency to recovery at a certain stage, which the student of therapeutics must always keep in mind. Although I have spoken of cold in continuation with damp as if it were the sole cause of catarrh it must by no means be supposed that this is the sole cause. With the changes in temperature there are, doubtless, frequently coincident and very influential certain electric disturbances, of which it is very difficult to take exact appreciation. To these we must refer the great prevalence of catarrhal and catarrho-rheumatic affections at certain seasons, and during the prevalence of certain winds. This prevalence is sometimes such as to suggest, as in the case of influenza, that the air must carry with it the particular and contagious germs. The sum total of what are included in the meteorological conditions termed weather must count as causes of catarrh. We have placed the rheumatic diathesis with the catarrhal and the scrofulous, as one which is universal, and in which all human beings share in some degree. What I have said as regards the laws of catarrhal inflammation apply very closely to those which are rheumatic, for the two are as regards their causes very nearly allied. Rheumatism like catarrh is usually transitory, especially when it occurs in the young. As with catarrh, so with it, when the aged are its subjects there is danger that it may become chronic or even permanent. Like catarrh, it may mix itself with scrofula or be modified by any other influence which disturbs the general health. The effect of malaria upon the system is often seen to much increase the proclivity both to catarrh and rheumatism. One other diathesis so very frequently mixes itself up with rheumatism, and the two in hereditary transmission become so intimately united that it is a matter of con-

siderable difficulty to ascertain how far rheumatism pure can go. We can, however, have little hesitation in admitting that it may be the parent not only of rheumatic fever, of transitory rheumatic pains in joints, fascia, and muscles, but of chronic crippling arthritis, in which almost all the joints are involved, and in senile periods of the slowly destructive arthritis which wears away the cartilage and eburnates the bones. Further, I think we may grant that it is not unfrequently the parent of sciatica and lumbago. All the affections which I have mentioned occur occasionally to those in whom there is no reason to suspect a gout complication; and, what is a still stronger fact, they are met with occasionally in the lower animals. Having said this I must not delay to add that in a great many of the exaggerated and peculiar forms of them which we witness in the human subject, the cause of the peculiarity is an hereditary complication of gout. When this complication exists it shows its power we may suspect by inducing a permanent modification of tissue; and it is to this modification that the peculiarities in the processes are due. Hence the impossibility under many conditions of discriminating between gout and rheumatism. We can for the most part easily tell in any individual case what the causes which have provoked the attack have been, and we can assign them on the one hand to those of rheumatism or on the other to those of gout; but we cannot estimate with any chance of certainty the previously acquired proclivities of the tissues. There is yet another source of fallacy that we are by no means always acquainted with—the condition of the patient's health at the time of the attack. If a patient already predisposed to gout in his kidneys, his tissues, or his blood be exposed to the exciting causes of rheumatism he will have one of those attacks which you yourself, Sir, have so well described, and about the nature of which there has been some controversy. There will be difference as to whether such an attack should be called rheumatic fever or generalised gout; and the solution of the question is, I suspect, to be found in the fact that it is both.

Two sets of causes have been at work, and the result has been a mixed one. When a little white tophus is seen on the ear the merest tyro can read its lesson, and the veriest sceptic dare not refuse its revelation. It is both retrospective and prospective in its significance; we know that the patient's kidneys have become unsound, and that he has failed in the past in the due depuration of his blood. We know that this loaded blood condition must have put him in danger of attacks of arthritis; and that in all probability he has suffered on many occasions from acute and very painful inflammations of some of his smaller joints. We know further that changes have taken place in many of his tissues, and especially that the walls of his blood-vessels have become thickened. Looking into his future we know he is in danger not only of other attacks of arthritis, but that, however carefully he may restrict his diet and manage his mode of life, it is probable that the renal and arterial changes will increase, and bring with them their peculiar inconveniences and risks. We know further that if a man in such a state should have children, they will, in spite of the utmost care in avoiding the dietetic causes which originally produced it, inherit some of the peculiar tendencies which he had acquired. Where the inheritance will stop, how far it is possible for one structural peculiarity to be separated, and to be inherited apart from others, we do not know. There is, however, I would suggest, good reason for believing that in families in which, either by accidentally changed conditions, or by intelligent foresight, several generations have been carefully exempted from the causes of gout, its existence in times long past may still be shown in the perpetuation of one or other more or less isolated tendency to structural disease. It is under such conditions that not a few of the forms of rheumatic gout occur, although of others, and perhaps a large majority, it is rather the fact that the exciting causes of gout have by no means

been wholly suppressed. In this way we may have to recognise as the lineal descendants of gout maladies which occur in those in whom we can by no means prove its existence. I have referred repeatedly to the facts which favour the belief that the hæmorrhagic diathesis itself may, perhaps, belong to this category; and in a former course of lectures I analysed the facts contained in Dr. Wickham Legge's able little monograph on this subject. During the past year some very interesting facts have come under my observation, which serve to give support to it, and to lead to the conclusion that many, if not most, forms of intractable hæmorrhage are in connection with hereditary peculiarity of the arterial system, derived from gouty progenitors. I will mention only three, and very briefly. A gentleman who consulted me a few weeks ago, with cataract and diabetes, told me that he had been most of his life liable to very profuse attacks of hæmorrhage. In early life they had been alarming, and sometimes so frequent as to be almost constant. They were always preceded by a sense of weight and discomfort at the epigastrium; and, provided the hæmorrhage was not too profuse he had usually felt relieved by it. There was a strong inheritance of gout, and he had himself suffered from several attacks. A school-boy was sent to me by Mr. Harrison, of Braintree, on account of repeated and alarming attacks of epistaxis. They had been so profuse and so frequently recurrent that he had lost much of his colour and strength. The point, however, which most caused anxiety was that his elder brother had died of it. In him the liability had commenced at thirteen and a-half years, had persisted for two years, and finally, after continuing for four days, it ended in death. Their paternal grandfather had suffered much from gout, and their father at the age of twenty-two had had severe epistaxis. In the case of a lady, now aged twenty-nine, and much out of health, I had the following history:—She had always suffered from indigestion and rheumatic pains. At the age of seven she had epistaxis to such an extent that the nostrils had to be plugged; and in spite of that measure for three days, it was expected that the attacks would end fatally. She once had bled to an alarming extent in consequence of tooth drawing; and her first menstruation soaked the bed through; and ever since this function had been attended with losses so profuse as to have greatly enfeebled her. There had been much gout on both sides of her family, and she herself had had symptoms very like it. I was unable, when examining this subject last year, to agree with Dr. Wickham Legge in his opinion that cases of remarkable tendency to hæmorrhage, occurring, as it were, spasmodically, should be quite apart from the hæmorrhagic diathesis in which we observe the tendency to prevail in direct descent through many generations. It may be that as a matter of convenience it may be well temporarily to effect this separation, but it must, I think, be with the clear understanding that it is a conventional one. The hereditary cases are those in which the idiosyncrasy has become definite and established; the others show us the idiosyncrasy in connection with its original causes, and, if I may so express it, in process of breeding. The cases of hæmorrhage into the vitreous in young men suffering from constipation which had been collected by Mr. Gales, of Birmingham, and in many of which no history of gout could be obtained, go with other facts to make it probable that tendencies to bleed are sometimes met with in association with other causes. My own experience as to retinitis, hæmorrhagic blood patches in the conjunctiva, cerebral hæmorrhagic epistaxis, and other allied disorders lead me to attach very great importance to the history of inherited gout as their cause.

There is one subject which it is impossible to leave out of the account in our estimation of the diathesis. It does not constitute a diathesis in itself, but it com-

plicates them all. I refer to the changes in the state of the nervous system, or quality of the nerve force which we know as tone. By that word I suppose that we mean the power of producing nervous energy. If we speak of the tone as low and poor, we mean that there is but little vigour in resisting irritation, and that comparatively slight influences will evoke a large amount of disturbance. That vigour depends, no doubt, upon the state of nutrition of the nerve-cells themselves, and it may vary much in different parts. Thus, the tone may be diminished in one nerve district and yet be good in others, whilst in some instances it is reduced in all, simultaneously. A condition of great general exhaustion is by no means, however, always equivalent with a state of low tone; it is necessary that the enfeeblement should pertain to the nervous system especially, in order that that term should become applicable. Perhaps it is further true that in most of the conditions in which derangement of tone is in question, the disturbance or enfeeblement has reference chiefly to that part of the nervous system which controls the circulation. Whenever the circulation is specially liable to reflex derangement and congestions, or their opposite occur with unusual facility, we are safe in declaring that the tone is low. It is part of the business of the nervous system to duly regulate the supply of blood to various parts to prevent local arterial spasm, and under the varying conditions of daily life to maintain the normal balance of circulation. When this power is deficient the various causes of disease act with greatly increased effect. In many cases loss of tone may be so long continued and so great that we cannot but suspect that it depends upon degenerative and permanent changes in the nerve cells. Not only may loss of tone aggravate the diathesis, but many of these act very efficiently in producing loss of tone. Thus the influence of malaria is very definite in this direction, and is felt through very long periods. But I cannot for the present dwell longer on this part of my subject.

The present is, perhaps, the most suitable place for me to interpolate two emendations in former lectures. In my first lecture I adverted to the want for purposes of estimation of the relative frequency of the different complexions in the British population. In doing so, I omitted to mention the excellent work accomplished some years ago by Dr. Beddoes, of Bristol. I had intended to mention it, and should certainly have done so if I had remembered its extent and value. In a subsequent lecture I urged the importance of life records, which should be kept in advance, ready to be produced to any medical man who may be first consulted, and especially comprising mention of idiosyncrasies of the individual, and the diseases which have been passed through by the individual. In making this suggestion, which has long occupied my thoughts, I was not aware that the Collective Investigation Committee of the British Medical Association already has in hand a scheme for its realisation. I have since with great pleasure been informed that such is the fact.

It is time that I should bring this lecture to a close, and with it will end my present course. In doing this, I desire, gentlemen, to thank you most sincerely for the very courteous attention with which you have listened to what I have advanced. Permit me at the same time to attempt a very brief *résumé* of the principal arguments.

We began by a glance at the very praiseworthy and to some extent successful attempts made by our forefathers by looking into a man's face to determine therefrom his physical peculiarities and his liabilities to disease. On examining the facts supposed to indicate temperament I was obliged to conclude that part of them were merely the characteristics of different races; and another fact, merely the products of past disease—personal or inherited. Thus it seemed that if race took its share of disease that which legitimately belonged to it, there was very little left to be classed

under the head of temperament. As regards disease, I suggested that the plan most likely to be productive of good results is to classify the chief groups of morbid influences, and to endeavour then to associate with each the separate maladies and tendencies which are dependent upon them. To this object our last three lectures have been devoted. We had previously endeavoured to clear the ground somewhat by placing in a separate category a large number of symptoms and of morbid manifestations which take their origin in individual peculiarity, quite apart from any recognisable tendency to disease. I insisted that the domain of mere idiosyncrasy is very large, and that these peculiarities may have had their origin remotely in disease. They have often existed for many generations in complete freedom from any such association. Whether I have succeeded in convincing you that it would be a convenience in medical teaching and practice to revive the old doctrines of diathesis I do not know. To my own mind it does appear, I may confess, that the states to which I have sought to apply that name are realities which it is very desirable to recognise. It seems to me, also, that the habit of naming diseases as if they constituted separate and complete studies has often a narrowing effect upon our conception of pathology, and leads to the overlooking of special causes. My endeavour has been to look at diseases not exclusively from before, but, so to speak, to get behind it and trace its origin. Classification should surely depend not upon external similarity, but relationship in cause. We should seek to place diseases in natural groups in connection with their ancestral descent. The attempt to do this has, I fear, sometimes led me into speculations as to the genesis of the different forms of diathesis which have seemed somewhat transcendental, and possibly a little wearisome. I can only plead that I have done my best to avoid these faults, and I have been endeavouring to thread my way through the mazes of a most complicated topic. The main conclusions as to the diathesis which I have suggested for your acceptance are these:—That there are three great universal diatheses dependent upon the very commonest causes of disease by which man, and not man only, has been assailed from the most primeval times. Close to these come others of far less importance, but of parallel nature, because they comprise us all in their range of liability; the diathesis of senile degeneration and the diathesis of malignant new growths. Next we have certain very important ones which are widely spread, but by no means universal, since they depend upon local exposure or personal habits. In this class we have the ague or malarial diathesis, the diathesis of rickets, those of bronchocele, scurvy, leprosy, pellagra, and gout. Respecting the diathesis due to malaria, I have some doubts whether it ought not to be admitted to the dignity of a primary or universal diathesis. If we go far enough back, probably the whole human race has been submitted to its influence, and not less probably has some impression from it been stamped upon us all. It may even be doubted whether now, in our advanced stage of civilisation, those who are apparently not exempt from all possibility of influence from marsh miasm may not still, in some minor degree, suffer from it. It is very possible that, although the severity be far below what is needed to produce an intermittent, yet that the well-recognised ill-effects of certain winds quite disproportionate to their chilly power may be due to slight impregnation with malarial poison. As to the diathesis of gout, I have suggested that it is but rarely of pure breed. Very often it builds on the foundations laid by other maladies, and however much it may boast itself the *dominus morborum morbus dominorum*, it is, if we can see it aright, very often merely a complication of plebeian rheumatism. Other diatheses have been mentioned which it is difficult to place in any definite arrangement. That in which there is remarkable tendency to hæmorrhage I have associated, for the most

part, either directly or remotely with the disease of the arterial system induced by gout. That which is characterised by failure of nerve tone I have linked in a like manner—not invariably, but still very commonly—with the influence of the sexual system upon the general health. So also of the state characterised by undue mobility of nerve force or emotional susceptibility known as hysteria. That there are hereditary diatheses which are characterised by peculiarities in the state of the different viscera, or of specialised systems, has also been suggested. In this category we have the hepatic diathesis, the diathesis denoted by chilblains, and that in which the vascular system generally is very feeble; and there results the liability to venous congestion in exposed and distant parts—even to gangrene of the extremities. I made no attempt at completeness in the enumeration of the diatheses, for it is clear that a little ingenuity might subdivide or define them to an almost endless extent. The description of a fresh diathesis is, in fact, almost as easy as the discovery of a new nerve centre, and perhaps much easier than the revelation of a new bacterium. Let me not be thought to speak in the least slightly of modern investigations in the two latter directions. I simply couple them with the attempts made to classify morbid phenomena, and to say of them all that they are, for the present, tentative, and that the experience of the profession in the future must assign their real value.

Finally, I think I may claim in all that I have said as to idiosyncrasy and diathesis, that I have done my best to recognise the power of hereditary transmission, and to insist that we ought to study disease as being, not of recent origin, or in dependence solely upon existing influences, but rather seek truthfully to "read the record of its long descent."

Again I must beg pardon, as I have already once done, for the fact that I have doubtless often appeared to be stating as somewhat novel things which were well known and almost commonplace. I could not possibly, from the nature of my subject, have avoided this, nor, indeed, have I made much attempt to do so. It is abundantly sufficient for my ambition if, availing myself most thankfully, so far as my knowledge extended, of the labours of those who have gone before me, I have succeeded in any degree in making opinion more definite, and giving emphasis to that which is true.

A CASE OF COMPOUND RE-FRACTURE OF THE PATELLA, IN WHICH THE FRAGMENTS HAD BEEN ALREADY SUTURED. (a)

By WILLIAM THOMSON, A.M., F.R.C.S.I.,
Surgeon to the Richmond Hospital, Dublin; lately Examiner in Surgery, Queen's University, Ireland; Member of the Surgical Court of Examiners, Royal College of Surgeons, Ireland, &c.

THERE are few subjects in surgery over which more battles have been fought than the treatment of fracture of the patella. The ambition of many surgeons is directed to the attainment of bony union, which they deem an absolute necessity in such cases. Apparatus, great and small, complicated and simple, have had their inventors and upholders; but all, it must be confessed, have had pretty much the same result—failure. Transverse fracture of the patella is an obstinate accident; it steadily resents interference, until not a few have come to believe in the treatment which is practically summed up in leaving matters alone. Within the past few years, however, the subject has taken a new development; and now we are not unaccustomed to hear of suture of the fragments with silver wire—not only as a proceeding suitable in cases which have resisted other treatment, but as justifiable immediately after the accident.

(a) Read before the British Medical Association at Worcester, August, 1892.

It may help to throw some light upon a difficult subject, if I submit the sequel history of a case in which such an operation was performed—the first, I think, in which we are able to examine the actual parts involved in what was regarded as a successful surgical proceeding.

I was sent for to my hospital, late one evening, to see a man who had just been brought in, and who was the subject of a very remarkable accident. He was aged about thirty-six, and had filled the position of first officer in a large foreign going ship. I found him lying in bed, suffering from an extensive rupture of the knee-joint. There was a great gaping wound running directly across the knee, extending from condyle to condyle of the femur, with edges as sharply defined as if they had been made by a surgeon's knife. The patella was broken transversely; and, as the patient could not extend the limb, and the thigh and the leg lay at about right angles to each other, the condyles of the femur and the articular surface of the tibia were fully exposed. There was considerable oozing. As the case was one requiring very careful consideration, I determined to consult my colleagues next morning; and meanwhile dressed the wound with thymol gauze, &c.

The history I received from the patient was an interesting one. He had been operated upon by the late Mr. Amphlett, of Charing Cross Hospital, London, about a year previously. I subsequently wrote to that gentleman, not long before his lamented death, and received from him a letter, of which what follows is a portion.

"T. G. came under my care last autumn, while I was taking charge of the Seamen's Hospital, Greenwich, during Mr. Johnson Smith's absence from home. He had, about three weeks previously, fractured the left patella, for which he was treated at a foreign hospital (Amsterdam). When he came under my care, there was a very wide separation of the fragments, and the patient experienced the very greatest difficulty in locomotion on this account; and, as it did not seem to be a case at all suitable for help by means of any mechanical appliance, I (after consultation with my colleague, Mr. Davies-Colley) determined to make a resection of the broken fragments of the patella. This I accomplished, drilling the ends and passing stout silver wire. I effected drainage by means of two tubes passed right through the joint. The patient did very well—the temperature only rising to 100° 3'. Some time afterwards, the wires were removed, and the fragments appeared to be united by bone. The joint, however, remained stiff."

Mr. Amphlett further said he had notes of the case, which he asked me to supplement; but I regret that his sad death disarranged our designs.

The patient stated that, after he left Greenwich, he gradually improved; but the joint had hardly any motion. It was slightly flexed, so as to cause him to walk on the anterior part of the foot, and he was unable to pursue his occupation. On the evening of the accident, he was leaving a shop; and when stepping down to the pavement, his toe caught some obstacle; the limb was violently flexed as he tried to save himself from falling. He at once felt something snap, and an examination showed what terrible mischief had been done.

After a full consideration of the case, we believed that excision offered a fair chance of success. This was accordingly at once performed. The fragments of the patella, and thin sections of the femur and tibia, were removed; and the limb was put up in a thymol dressing and in a plaster-of-Paris splint. The subsequent history may briefly be told. There was a good deal of suppuration, but there were no serious symptoms at the time; and the patient left hospital in eleven weeks, with the wound perfectly healed, a limb about three-quarters of an inch short, and much more useful than before the accident. I have seen him frequently since. He was able to lay aside artificial support soon after he left the

hospital, and he walks so well that his lameness is hardly perceptible.

The fragments which were removed are now upon the table. They consist of the fractured patella and sections of the femur and the tibia. The latter two present examples of fracture *par écartement*. On the tibia, just at the termination of the anterior arm of the external semilunar cartilage, is a thin plate of bone about the size of a sixpence, which has been torn out of a corresponding depression in the inner margin of the external condyle of the femur. The piece of bone is movable, and is attached to the tibia by a short fibrous structure. Just in front of the spine of the tibia is another minute piece: and along the inner margin of the articulate surface, and somewhat anteriorly, is a strip about three-quarters of an inch in length and a quarter of an inch wide, from which bone has been torn. Finally, on the femur, about midway between the condyles, is a nodule of bone on a fibrous stump, torn from a depression half an inch in front of the spine of the tibia. The articular cartilages are smooth and healthy. The external inter-articular cartilage is perfect; but the inner one has disappeared altogether.

The patella itself is in two fragments. The fracture has taken place nearly in the line of the old injury; but there can be no doubt that osseous union existed in the bone after the original operation. Four holes remain (two above and two below the line of fracture) to indicate the position of the wire sutures. Union had taken place for about two-thirds of the distance across. Beyond that is a separation between the portions of the patella amounting to one-third of an inch. The fracture was almost extra-articular, only encroaching on the line of cartilage to the extent of half a line. The cartilage has nearly altogether disappeared, except round the margins.

This case presents many interesting features, and suggests some questions which it will be of advantage to consider. The character and the extent of the injury are remarkable. The fracture was not produced in the ordinary fashion, by muscular contraction, but very much in the same way that a long bone may be broken in its shaft by some violence applied at its distal parts. The difference I make is that here the patella was fixed by the adhesions which had been set up after the operation, and entered into the formation of the practically ankylosed articulation. The whole joint was fractured; and the patella, as a constituent part of it, yielded to the same force, but not to the contraction of the quadriceps extensor muscle. The extent of the wound was also remarkable, for it reached from condyle to condyle; so that, when I came to excise the parts, I found it unnecessary to enlarge it in that direction, and had simply to convert it into an H by making an incision at each extremity of it. The rupture of the soft structures in this way was due to the previous operation. The integument had become adherent to the patella and other parts; it was very tense over the slightly flexed joint; and, when that flexure was increased, there was no possibility of the already much stretched skin resisting the sudden strain.

I am not aware of any case precisely similar to this; that is to say, of compound fracture of the patella (or rupture of the knee-joint) after bony union has been attained in the same bone for a previous fracture. This bursting of the knee-joint has occurred, however, on a few occasions, under somewhat different circumstances.

The late Mr. Poland, of Guy's Hospital, London, records a case in which a man had a wound on the patella about three inches and a half long, exposing the bone. The case progressed favourably, and the wound was nearly cicatrised, when, eight weeks after the first accident, he fell, tearing open the wound and fracturing the patella, so that the joint was opened. An attempt was made to save the limb by bringing the parts together, but pyæmia followed, and ultimately the

patient was saved by amputation (*México-Chirurgical Transactions*, 1870).

Mr. Poland says he has only found one case in the practice of Pelletan bearing a strict analogy to the foregoing. There was, first, a wound, which was healed; and three months afterwards the patella was broken, and the newly cicatrised wound torn open. The parts were brought together; but gangrene threatened—there was delirium—and the patient died on the twentieth day, no opportunity for amputation having offered (*Clin. Chirurg.*, tome ii, p. 155).

In Sir Charles Bell's case there was fibrous union of a fractured patella, then rupture, laying open the joint. Immediate amputation followed (*Operative Surgery*, by Sir C. Bell, vol. ii., p. 204, pl. v.).

Dr. Croker King mentions a similar case. There the patient refused secondary amputation and recovered (*Medical Press*, December 8th, 1847, p. 353).

Cases of compound fracture of the patella, from whatever cause arising, are fortunately of comparative rarity, for the mortality is at least 25 per cent.; and as to the rest, very few indeed recover with perfectly useful joints. Mr. Poland, in the paper already referred to, has collected sixty-nine cases of this injury, including gunshot wounds. In twenty, the fragments of the patella were removed at once, with three fatal results; there was one secondary resection of the joint; four primary amputations, with two recoveries; and five secondary amputations, with four recoveries. Several recovered with stiff joints, after passing through long periods of suppuration.

The treatment pursued in this case may be questioned, especially by those who believe that, under the conditions of antiseptic surgery, wounded joints are not of serious moment. But we had here to weigh the probabilities of recovery by a treatment which would have consisted in bringing the fragments together and waiting for repair, or by the removal of the articular portions and the bringing together of vivified surfaces of bone, as in excision. Between these I had no doubt as to the course to be pursued. The joint was already a disabled one; it had lost its natural movement; it had been freely exposed to septic influences; and the result at best would have been ankylosis in the flexed position. But that ankylosis would have been reached through the tedious process of exfoliation of the cartilages, with all the attendant dangers of suppuration. The shock to the patient was but very slightly increased by removing the ends of bones already fully exposed, while the probability of speedy recovery, with a sound and healthy ankylosis was rendered more sure.

But another and more important question is suggested by this case, and that is, as to the treatment of transversely fractured patellæ by cutting down upon the fragments, and directly suturing them by silver wire. This method of dealing with such accidents appears to have been first practised by Professor Cooper, of San Francisco. In the *Medical Times and Gazette* of November 2, 1861, he writes:—"Our method of treating transverse fractures of the patella, and one which has thus far been invariably successful, is as follows. Make a longitudinal incision of sufficient length to expose the fragments; drill the anterior margins of them with a drill one line in diameter; then pass a silver wire through the holes thus made, and, by crossing the ends and pulling stoutly upon them, bring the separated parts together. A knot is then made by twisting the ends of the ligature together, which holds the fractured portions of the patella in apposition, by which a bony union always takes place." As essential to success, he insists that the wound be healed by granulation, and not by first intention. Lint should be placed in the wound, and the limb tightly bandaged from the toes to the middle of the thigh. The wires are removed about the sixth or eighth week.

Dr. Hector Cameron, of Glasgow, was the first in this

kingdom to perform the operation, protecting it by all the safeguards of the Listerian method, and he has since been followed by many surgeons not only here, but on the Continent and in America.

Now we have arrived at a time when suture of the patella is advocated and practised not only in cases of non-union, but in every instance as a regular treatment. But when we come to look at the results which have been obtained, we are not impressed by the magnitude of the success. It is true that the patients generally recover, but some of them narrowly escaped death, and such a risk would demand a very considerable advantage as its reward. In the cases reported by Henry Smith (*Lancet*, August, 1878), Rose (*Lancet*, November 22nd, 1879), Royes Bell (*Lancet*, November 1st, 1878), Holmes (*St. George's Hospital Reports*, vol. x., 495) Lister (*British Medical Journal*, June 11, 1881), movement of the joint was retained in a few instances, but it was not apparently free, and patients are described as walking with a slight limp, using a stick, and so on.

Is a fractured patella, united by ligamentous bonds, which afterwards stretch, so great a misfortune after all? I have never seen a case of osseous union in a living subject, and I have never seen a case in which a patient was disabled to any great degree by his fractured patella. Every surgeon has met with cases which get on very well without bony union, and without any special apparatus. I do not mean to say that in no instance ought this operation to be done, but I think it ought only to be recommended where the injury has become an absolute impediment to the patient's progression. In the present case, at all events, the man's position was not improved. He had a too flexible joint before the operation and a stiff flexed one after it, a condition which might have been practically secured by a properly adjusted knee-cap. Moreover, I think we render these persons so operated upon often liable to such an accident as is here reported; for we may have, instead of movement, a spurious insecure ankylosis, with a joint covered by cicatrised and tightened integuments, liable to rupture on very slight provocation.

If, however, the operation in such cases should be rarely resorted to, it seems to me that it cannot be justified in recent accidents. Experience shows us every day the admirable results which may be attained by simple methods, and the facility with which persons with broken patellæ may pursue their avocations. Is it to be laid down as a rule that we are to wipe out such probabilities altogether, and to lay open a man's joint at once? If we could be assured of perfect motion with perfect union the justification would be strong, but who can assure us? Passive motion is always late and limited, because we cannot disturb the uniting fragments; and, meanwhile, changes are being effected in the synovial membrane, the cartilages and the ligaments generally, which may end in giving us a much worse joint than if we had left it alone. I am quite conscious of the great advances in operative work which the Listerian method has allowed to be made; but, thorough believer as I am in its efficacy and its complete safety where accurately carried out, there are risks which will always surround it, as they surround every scientific method. It has enabled us to do great things, but even with its help I cannot believe that we are justified in attempting to do what is unnecessary, when that proceeding is attended not only with danger to limb but to life also.

ACCORDING to the last official weekly return, the death rate was higher in New York than in any other large city in the world; reaching the very high figure of 46 per 1,000 of its inhabitants. This excess was mainly attributable to diarrhoeal diseases amongst children, and not to the epidemics of diphtheria and scarlet fever, which have now happily passed away.

OUT-DOOR VERSUS IN-DOOR MATERNITY CHARITIES.

By J. E. BURTON, L.R.C.P. Lond., M.R.C.S.,
Physician-Accoucheur to the Liverpool Lying-in Hospital.

(Concluded from page 152.)

Now we have seen that there is a vast difference between the results obtained in outdoor and indoor maternity charities, we may inquire into the causes for it. Mr. Owthwaite, the secretary of the City of London Lying-in Hospital, has mentioned most of them.

First and second may be comprised under the heading accuracy of records. This has already been disposed of in the case of the four institutions mentioned just now.

3rd. Greater proportion of primiparæ in hospital cases.

4th. Greater proportion of difficult cases in hospitals.

To these I would add (5) Greater proportion of innuptæ in some hospitals.

6th. Propagation of infectious or contagious disease.

Now, such charities as those already mentioned—the Newcastle, Manchester, Birmingham, and Royal Maternity—must take all the cases that come. If they send their primiparæ and difficult cases into hospital they do not get rid of them, and they still run the risk of having their death-rate raised by them, so that a comparison of these charities as a whole with mixed charities, such as the City of London and British Lying-in Hospital, will be a perfectly fair one. The only other maternity charity whose outdoor and indoor results would be useful in making such a comparison is that of Glasgow, but this institution is not available for the purpose, as a most important element would make the comparison misleading. This institution takes in unmarried women, and the destitute of all kinds, so that a comparison with those whose "charity" (†) is only extended to the "moral" is obviously out of place.

The two charities selected give us a total of cases of labour amounting to 11,194, and the deaths number 77. This gives a death-rate of 1 in 145, against 1 in 364 in institutions treating exactly the same classes of cases, and whose statistics are thoroughly reliable. Lest it may be argued that labour is a less dangerous process in the north of England, and that the comparison is valueless as showing the relative safety in home and hospital confinements on that account, we may compare these 11,194 deliveries and 77 deaths with the 13,515 deliveries and 45 deaths of the Royal Maternity Charity, bearing in mind that the institution showing the better results has no advantage of time or locality, for these are the same in both.

The influence of illegitimacy in raising the maternal death-rate is difficult to measure. All writers on obstetrics who have mentioned the subject seem to agree in considering illegitimacy as constituting an element of danger during the puerperal processes. This would lead us to expect that those hospitals that admit such women would have a higher death-rate than those that exclude this class of unfortunates. The hospitals that admit such women are the General Lying-in Hospital in York Road (after investigation by the Charity Organisation Society), Queen Charlotte (women with their first child), the Glasgow and Edinburgh Maternity Hospitals, the Rotunda Hospital, Dublin, and the Coombe Hospital. The four last named seem to think that "the quality of mercy is not strained," or should not be. This is the highest charity, in that it falls like the rain, on the just and on the unjust.

The number of labours, then, in the hospitals admitting single women was 7,841, and the deaths were 150, or 1 in 52, whilst the number of labours in hospitals admitting married women only amounted to 4,654, and the deaths numbered 77, or 1 in 58. These two death-rates show a difference between them of nearly 5 per 1,000. A perusal of the reports of some of the charities would lead to the conclusion that seduction had a powerful influence over the issue of the course of labour and childbed. Thus, in the Rotunda Hospital in the year 1875, out of 27 deaths 9, or one-third, were in cases of seduction. The fact, then, that single women are treated in so many lying-in hospitals

should be taken into account in a comparison of the two classes of charities, for although some of the outdoor maternities may treat single women, only very few of them do, viz., the General, Queen Charlotte, the Rotunda, and the Glasgow Maternity Charity. [Of course I am speaking here of those maternities only that are mentioned in the above tables.] The number of cases reported from these four maternities, of which we have returns, is but trifling, as from three of them the returns of one year only have reached us. Unmarried, moreover, having no home, would naturally be admitted, as a rule, into hospital rather than be attended by the extern department.

We have now considered briefly most of the reasons why indoor maternity charities, as a whole, may be expected to have higher maternal death-rates than outdoor maternities.

The first and second, as has been already stated, may be comprised under the head of greater accuracy of records.

3rd. Greater proportion of primiparæ in hospital cases.

4th. Greater proportion of difficult cases in hospital.

5th. Greater proportion of single women in hospitals.

But we have not yet considered (6) the greater danger from propagation of infectious or contagious disease, comprised under the head "Hospitalism," or aggregation.

Before commencing this part of the subject, I should like to throw out a suggestion, which, if acted on, would, in a few years, put us in a position in which we should be able to arrive at much more definite and certain conclusions with regard to the various points in connection with childbed maternal mortality than we possess at present.

In looking over the returns of the different charities it is bewildering to notice the various modes in which the results are notified. Each charity follows its own particular plan, or, but too frequently, no plan at all, so that, taken as a whole, the result is both exasperating and disappointing. My suggestion is this: That the Obstetrical Society of London, or that of Dublin, or both in conjunction, should devise and publish a plan, and that all the officers of the different maternities whose duty it is to record the statistics should be requested to do so after the method of the plan approved of. Our charities would then be assisting in a great work, and be in some measure giving some scientific return for the time, trouble, and money expended on them.

In trying to estimate the importance of "aggregation" in determining the maternal death-rate in childbed, I shall compare the statistics of charities as nearly as possible similar, that is, each class shall take its own bad and difficult cases and its own primiparæ. Those that take in single women will have to be left out, as there are, alas! no outdoor maternity charities treating single women with which to compare them. From this comparison the General Lying-in Hospital must be excluded, not because its figures are so good, and because I shall consequently be afraid to make use of them lest they should mar the result I expect to arrive at, but because the figures are for one very exceptional year only. To prove that the figures are exceptional, I have only to state that in 1880 there were 3 deaths, and that the hospital was closed during the greater part of the year 1879. St. John's House, Chelsea, and the Birkenhead Lying-in Hospitals must also be omitted, as in the former there can be no aggregation of cases, as every patient has a separate room, whilst in the Birkenhead Hospital the cases are so few that, taking the average length of stay of the patient in hospital to be ten days, there will be four days out of every fortnight during which there will be but one patient in the house. The only institutions remaining, then, for comparison are the City of London Lying-in Hospital, the British Lying-in Hospital, and the Belfast Lying-in Hospital, on the one side (Group 1), and the Birmingham Maternity, the Newcastle-on-Tyne Hospital and Charity, the Royal Maternity Charity, and the Manchester St. Mary's Hospital Maternity on the other (Group 2). In the former group we find a total of 11,413 labours and 77 deaths, or 1 in 148; in the latter group, 29,520 cases of labour and 79 deaths, or 1 in 373. I do not think there is anything unfair in this com-

parison; it is simply one between a group of maternity charities that does not aggregate cases, and another group that does. The maternal death-rate in the one group is 2½ times as great as it is in the other! This great difference cannot in this case be explained away as is so often done by saying the figures are not correct, for it has been shown that in the case of the four charities forming group 2 the statistics are thoroughly reliable. Neither can the difference be explained away by attributing it to the greater proportion of difficult or dangerous labours in group 1, for each group treats the whole of its own difficult and dangerous cases. Neither will the explanation that group 1 has a greater proportion of primiparæ serve, so that at last we have to fall back on "aggregation," or "hospitalism," as the cause of the excess.

It matters not how this excess arises; the fact that the maternal death-rates in hospital have, on the whole, been excessive hitherto, ought to be faced, and not shirked nor explained away. The excess undoubtedly has been there, and at present we have no proof whatever that it has vanished.

I had intended to discuss the subject on another side, namely, by dividing the causes of maternal deaths in childbed into three classes—1. Puerperal causes, pure and simple; 2. Septic puerperal causes; and, 3. Strictly non-puerperal causes, and then ascertaining the ratio that class 2 bears to the whole number of labours in each group, but I have no data to work upon.

Enough has been said to show, however, that there is, and has been, a very great disproportion between the maternal death-rates of charities that do not aggregate their maternity cases and those that do. There has been a very great disposition shown on the part of physicians to these institutions to minimise and explain away everything that makes an unfavourable show. If the death-rate has been high, as it almost always has, the utmost pains have been taken, pages upon pages have been written, the health records of the whole town have been ransacked to show *what the cause was not!* that the high death-rate did not arise from contagion or infection, and that, consequently, the hospital was not to blame. But this is not enough; they must prove that such a high death-rate does not exist. If they cannot prove this, their first endeavour should be to find out what is the cause of it, instead of what is *not*.

I am perfectly ready to admit that the maternal death-rate has been considerably diminished in some hospitals during the past few years, and that others have for many years enjoyed a remarkable immunity from contagious and infectious diseases. As an instance of the former, I may mention the Charité Krankenhaus, Berlin, of which Gusserow is the director. In the years 1859-60 the maternal mortality in this hospital was 16 per cent. In 1874, when the antiseptic method of treatment was first adopted, it fell to 4.1 per cent., and in 1878, when Gusserow first took office, it was 2.6 per cent. In 1879 the mortality was reduced to 2 per cent.; in 1880 to 1.6 per cent.; and in 1881 to .9 per cent. This is not only gratifying, but encouraging, and it is to be hoped that the talented physician to the hospital will not be content to let the rate of maternal mortality stand at 1 in 111, the point now reached, but that it will approximate yet nearer to the rate prevailing in outdoor maternity charities.

As instances of lying-in hospitals that have enjoyed a remarkable immunity from contagious and infectious diseases, I know of none more striking than the lying-in wards of the Liverpool workhouse and the Belfast Lying-in Hospital. It is true that the Liverpool workhouse is not a maternity charity, but it is an institution in which maternity cases are aggregated, and some attempt to ascertain the causes of the good results arrived at may be instructive as well as interesting.

For the last eight years about 300 patients per annum have been confined in the lying-in wards of the hospital, and during this period the death-rate has been 1 in 300. The causes that are supposed to have helped in attaining

these good results are briefly as follows :—Every woman on admission into hospital, unless too far advanced in labour, is put into a warm bath, and afterwards clothed in hospital garments. If the labour has already advanced so far that the bath cannot be made use of she is still washed all over and clothed in hospital garments. Such as are not actually in labour are admitted into a "waiting" ward, which serves as a place of quarantine. If any infectious disease is present it will probably show itself, and measures can be taken accordingly. Again, whether the woman is admitted into the "waiting" ward or not, she is a pauper, and as such has been visited by the relieving officer, and it will be known to a certainty whether there is infectious disease in the house in which she has been residing or not. In these two ways the risk of introducing infectious disease into the labour wards is reduced to a minimum. Again, every woman on being admitted into the labour ward, whether she comes in from the waiting ward or direct from the outside, is placed on a new straw bed, one that has never been lain on before, so that she cannot be brought into contact with the putrid or putrefying discharges of any other person. Twenty-four hours after completion of the labour her linen is changed throughout, she is placed on a second new bed, and then removed into the lying-in ward. After remaining in this ward a week, her linen is again changed; she is then placed on a third new bed and moved into the convalescent ward. The greatest stress is laid by Dr. Alexander, the popular visiting surgeon to the hospital, on the frequent replacing of the used beds by new ones. Although upholding the necessity of thoroughly and frequently disinfecting both walls and floors, he, however, thinks these of secondary importance as compared with the frequent change of beds. For the rest the arrangements are simple. The napkins used are washed in a carbolic solution. The discharges are received on carbolised tow laid on the napkins, whilst these in their turn lie flat on the bed beneath the genitals, and are not, as is usually the case, turned up over the patient's abdomen. This plan ensures a freer exposure to the air, and a consequent more rapid dessication of the discharges. The parts are frequently wiped with dry tow, but vaginal injections are never employed, unless the discharges become offensive. The temperature is carefully recorded night and morning.

If we now turn to the Belfast Lying in Hospital, we find that here the prophylaxis resolves itself into one very simple measure. That the results have been satisfactory is shown by the fact that not only was there no death among the 219 patients confined in it last year, but that during the last five years with an annual average of over 200 cases of labour, only two maternal deaths have occurred, or 1 in 500. As I have already said, the prophylactic measures are extremely simple. The only beds in use are common straw ones. The seam in the ticking runs up the middle of the bed, and on the upper side the seam is left open the length of the middle third. There is thus a large hole here where the straw is visible. This hole is useful in "making" the bed, as the hand can be put in to stir up the straw and make it soft and downy; but the principal object of it is that all the straw can be removed immediately it becomes soiled, and fresh clean straw introduced in its place. By this means no discharges remain too near the person of the lying-in woman. The beds themselves are changed frequently. Having visited this hospital recently, I may say that the wards did not look particularly bright nor fresh; the air in them was decidedly stuffy. On inquiry, I learned that carbolic acid was rarely used—I suppose because it was rarely required.

These two—the lying in wards of the Liverpool workhouse and the Belfast Lying-in Hospital—are two remarkable exceptions to the rule that wherever labour cases are aggregated there will be found a high maternal death-rate; they can in no way be looked upon as apologies for lying-in hospitals in general.

In conclusion, then, I think I have shown (1) that

in out-door maternity charities in the United Kingdom, certainly in England, the maternal mortality since the year 1875 has been very low, much lower than has been generally supposed; (2) That the maternal mortality in lying-in hospitals, on the contrary, has been high during the same period; and (3) That the difference between the two death-rates has not been due altogether or even mainly to any difference in the classes of cases treated—*e.g.*, unequal distribution of primiparae, difficult cases, &c.—but that it has been caused in some way or other by "hospitalism" or "aggregation."

If these conclusions are correct, it then behoves physicians to lying-in hospitals to find out the causes of the high death-rates, and apply the remedy in such a way that the death rates shall be reduced to the level met with in such out-door institutions as the Royal Maternity Charity, the Birmingham Charity, or the Manchester St. Mary's Hospital Maternity. If this is found to be impossible, there will then be but one course to adopt. If, on the other hand, it is found to be practicable, I venture to predict that the successful issue will be arrived at rather on lines suggested by the results of Liverpool and Belfast than by wholesale vaginal injections of carbolic solutions or delivery under the spray!

I wish to render my best thanks to all those officials of the charities mentioned in this paper who have kindly forwarded reports or otherwise supplied me with information.

Clinical Records.

RETENTION OF PLACENTA FOR FOURTEEN WEEKS AFTER ABORTION.

By J. E. BURTON, L.R.C.P. Lond.,
Obstetric Physician, Lying-in Hospital, Liverpool.

On the 21st of June last I was requested to visit Mrs. G., who was said to be very ill from protracted and copious flooding. On my arrival I learned that about the 4th of March, being then 4½ months pregnant, a discharge came on, which culminated about one week later in flooding and the expulsion of a foetus that moved. The flooding was so alarming that the medical attendant ("a homeopath") was called in, who examined the cast-off ovum, but as to his utterances thereupon I know nothing. The hæmorrhage subsided, but not completely—in fact, it never completely ceased till I saw her. It was at times very free, especially at the menstrual periods, and on several occasions, but not constantly, purulent and offensive. From a friend of the patient's I learned some more interesting (?) particulars. It appears that the lady was very averse from having a family, and during the course of a previous pregnancy had tasked her ingenuity to bring on a miscarriage. It seemed likely to her that violent movements and concussions might have the desired effect, and in order to test the soundness of her views she engaged in dancing and jumping exercises, jumping from chairs, &c., in her fond endeavours to rid herself of her plague. Finding these efforts unavailing, she went further, and finally got on the top of a chest of drawers and jumped down. But all was in vain; she could not dislodge the offender by these means, and she went her full term, and at last was delivered of what is now a beautiful boy, who rejoices in a poetic name. Towards the end of last year menstruation ceased, and for four months all her efforts to procure abortion were in vain. She, however, had that inestimable treasure—a female friend, to whom she confided her troubles and breathed her longings. "A friend in need is a friend indeed." (A quotation). This friend was the wife, or rather "grass widow," of a medical man, her husband living apart from her abroad. Acting on the instructions of her adviser, Mrs. G. now procured a long crochet needle and passed it up the vagina (this is her story—my own belief is that the "friend" did it), and some discharge came away. A day or two after the "lady friend" again called, and, being of a pious and heavenly-minded disposition, she devoutly knelt down by the patient's bedside and offered up "a most beautiful prayer" for her recovery. As has been already stated, one month after the "operation" the foetus

came away alive, but with its back "all mortified." The mother mentioned this little circumstance of the back of the victim being mortified quite complacently, and as being rather curious, but apparently without the slightest consciousness that in doing as she did she herself had been guilty of infanticide. But to return to the case. The hemorrhage had been so alarming that a neighbouring medical man had been already called in temporarily, who had checked the excessive flow. On examination I found an enlarged uterus, with a patulous os, and high up I could distinguish a spongy substance, having the feel of what is generally called a "mole." Not being able to remove it at the moment, I plugged the cervix with iodized phenol, and gave a subcutaneous injection of ergotine. In the afternoon a friend accompanied me and administered chloroform, when I first detached the intra-uterine growth from its site of adhesion with my forefinger, and then carefully removed it entirely with the ovum forceps. The substance on removal proved to be of the ordinary spongy trabecular structure. Had it been met with without a history of a fetus, or had the fetus died so early that it had become so nearly dissolved in its own liquor amnii as to have escaped unnoticed, most likely it would have been christened "molar" pregnancy. The case presented nothing further of interest.

Special.

BRITISH DENTAL ASSOCIATION.

THE second annual meeting of this Association has just been brought to a successful conclusion at Liverpool, after a two days' meeting, Friday and Saturday, August 25th and 26th. The Association, as many of our readers are aware, was established on the model of the British Medical Association, and with the object of watching over and promoting the working of the Dentists' Act. Although only two years old, the Association already numbers upwards of five hundred members, including the great majority of dental licentiates and surgeons practising dentistry. The meetings were held in the rooms of the Liverpool Medical Institution, which were kindly lent by the Council for the purpose. A large number of members were present, including most of the leading practitioners. In the absence of Mr. J. Tomes, F.R.S., President, owing to the illness of a relative, the chair was taken at the opening of the meeting by Mr. T. Underwood, Vice-President. Mr. Champion, M.R.C.S., of Manchester, the President-elect, was duly installed in the chair. The annual report, as well as the valedictory address of the retiring President, contained a vigorous protest against the conduct of the General Medical Council. It was pointed out that the Dentists' Act clearly indicated that the duty of the Council was to expurgate the Dentists' Register, and to strike off the names of the 400 totally unqualified practitioners who, in consequence of the lax administration of the Act, had been allowed falsely to register themselves. The Association had furnished the Council with the highest legal opinions to the effect that the names were illegally registered, and that it was the duty of the Council to erase them; but the Council had chosen to entirely renounce the judicial powers conferred upon it by the Act, and had refused even to consider further the correction of the Dentists' Register. A resolution expressing the regret of the Association at the attitude of the Council was carried. This business of the Association being concluded, and Mr. Spence Bate, F.R.S., having been elected President for next year, the scientific work was begun. Addresses were delivered by Mr. Charles Tomes, M.A., F.R.S., on Some of the Scientific Problems of Dental Surgery; by Mr. Henry Sewill, M.R.C.S., L.D.S., on the Etiology and Pathology of Dental Diseases; and by Mr. Norman Macleod, on Mechanical Dentistry. Other papers

were contributed by Mr. Coleman, F.R.C.S., Mr. F. Canton, M.R.C.S., and Mr. Oakley Coles, L.D.S.

On the evening of Friday the members dined together. Among the guests were the Mayor of the city and the principal local medical men, besides several of the leading practitioners from Manchester.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TREATMENT OF DIABETES BY BROMIDE OF POTASSIUM.—

Before the meeting of the Académie de Médecine a member read a paper on the treatment of diabetes by bromide of potassium. For the last six years the author has made this disease the object of his researches, and during that period he treated fifteen cases. He ignored entirely the classic *régime* of gluten bread, &c., being of the opinion that the disease consisted, not in the presence of sugar in the urine, but in the disorder of the organism, which produced the sugar in excess. Having had a patient who was diabetic, but who consulted him for certain nervous affections, he observed that under the influence of the bromide of potassium, of which he prescribed a drachm a day, the former disease yielded. This case gave him the idea to make experiments on rabbits, in which he produced artificially diabetes in touching the floor of the fourth ventricle, according to the method of Claude Bernard. Four grains of the drug injected into the veins caused the sugar to disappear in each case. Consequently, ever since the author has entirely adopted this drug in the treatment of the disease in question and always with good results. The author further insisted on the necessity of employing muscular exercise of every kind. The use of alkalies, and of iron, arsenic, quinine, according to their several indications, form part of the general treatment. There is one point worthy of remark in the above communication, and that is the complete disregard as to *régime*, which must be beneficial to the patient, in that he is relieved from the irksomeness of observing a certain imposed diet, which soon disgusts him, and what is more grave, keeps him continually dwelling on the affection from which he suffers, a fact which often leads to another malady, which, though less formidable, is not without producing a deleterious effect on the constitution, already weakened by the primitive disease, hypochondria. If further researches verify the efficacy of the observations of the learned author, the treatment of this grave affection will have made a *pas en avant*.

ABSCESS OF THE BRAIN.—Trepanning is an operation to-day almost entirely disregarded amongst French surgeons as being dangerous, and giving but rarely satisfactory results. However, M. Polaillon, at the last meeting of the Société de Chirurgie, related the case of a man on whom he practised the operation for an abscess of the brain. A man entered La Pitié on the 18th April last, aged 40, ill for a fortnight previously, and suffering from an intense nocturnal headache with parietal tumefaction. A medical practitioner saw the man before his entry into hospital, and diagnosed a meningoenkephalitis. The pulse was 40, and the pupils dilated. The surgeon opened a purulent collection situated over the fronto-parietal suture on the right side. The bone was denuded, and the probe penetrated through a small opening in the skull an inch and a quarter. On entering, the patient was in a position closely allied to stupor, the answers to questions were slowly given but precise, the memory was weakened, and there was hemiplegia of the face and members of the left side; sensibility was obtuse, but persistent. Swelling was still observed

over the suture already mentioned, and the patient was able to state that some days previously he received a blow in that region. Two days afterwards the position of the patient aggravated, symptoms of compression were evident, and coma threatening. M. Polaillon applied the trepan, which gave exit to about three ounces of pus; two days afterwards the trepan was applied a second time, giving issue to two ounces of a very thick matter; the probe penetrated an inch and a half into the cerebral substance. A drainage tube was placed, and the wound was continually washed with a solution of phenic acid. Two or three days afterwards the family of the patient came and took him away. He died on the 5th May, or ten days after the operation. The autopsy was not permitted.

HYSTERIA.—For some days past the daily journals have been full of a singular case of hysteria that is now the object of attention in the hospital Beaujon. It appears that one night the police found a young girl, aged 20, in an insensible state, lying on one of the seats of the boulevards. Not receiving any answer to the many questions asked, they brought her to the station, where she was examined by the police surgeon, who ordered her removal to the hospital. For several days after her entry she lay in a sort of stupor, taking no nourishment, and seemingly insensible to everything around her. A curious part of the affair is that she was *enceinte*, and before waking out of her lethargy, she gave birth, unconsciously, as she afterwards affirmed, to the child. Many medical men came to see her, and thinking that she was imposing, spoke in her hearing of police, &c., but she did not flinch; pins and needles were passed through her arms and legs, but she gave no sign of sensation. After repeated attempts to make her speak the charm was at last broken, when she answered the questions rationally, but soon got tired and relapsed into complete mutism. She said she did not remember anything of what happened, and was surprised to find herself in an hospital, as she was alone in Paris, her parents residing in the country. Accordingly, her parents were telegraphed for, and she will be given over to their care. The medical report on the peculiarities of the case has not yet been issued, but to the disappointment of some who thought that it was a miracle divinely given to the pagan city and to others who expected to have another edition of the "fasting girl" the verdict will not fail to be hysteria.

TREATMENT OF CHOREA.—Dr. Bouchut's treatment *par excellence* of chorea consists in the administration of hydrate of chloral in large hypnotic doses, even for children. He orders for a child of six years thirty grains in *one dose*, the dose to be repeated every day and increased if necessary to forty or even sixty grains. The effect of this dose is six or eight hours' profound sleep, during which the child does not stir. After a couple of days the disease abates, and in about a fortnight the cure is obtained.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Bombay 20, Madras 29; Paris 25; Geneva 13; Brussels 25; Amsterdam 19; Rotterdam 22, The Hague 22; Copenhagen 28; Stockholm 28; Christiania 32; St. Petersburg 44; Berlin 37; Hamburg 26; Dresden 31, Breslau 32, Munich 28, Vienna 21, Prague 24, Budapesth, 35, Trieste 37, Rome 25, Turin 23, Venice 30, New York 46, Brooklyn 37, Philadelphia 31, and Baltimore 30.

WEDNESDAY, AUGUST 30, 1882.

UNCERTIFIED CRIME.

THE large amount of consideration that is being given to the question of unqualified practice and the many evils that arise out of it, is gradually bringing to the front opinions which, though they may have been for a long time generally held, have never received such attention as is at the present moment accorded to them on every side. It is a remarkable fact, too, that in the discussion just now going on, conclusions apparently the same are arrived at along very different paths; and in illustration of this, no more remarkable instance has been afforded than is contained in comparison of the utterances, almost simultaneous, of two officials, the one coroner for the city of Manchester, the other holding a similar position in the borough of Leeds.

Mr. Edward Herford, city coroner for Manchester, recently addressed a letter to the President of the Poor-law Board in which he requests that gentleman to express his opinion to the Registrar General on the duty of avoiding "such encouragement to murder," as is offered by the acceptance of certificates of death granted by medical men in cases of which they can really know nothing, "where they have not even viewed the body after death, or where they have seen the deceased perhaps only for a few moments *in extremis*, and where they have every reason to believe the death has or may have been caused by violent or not natural causes." Mr. Herford

further goes on to state that "these medical certificates are too often acted on by the registrar, and thereby the legal investigation avoided, and thus impunity and encouragement given to secret murder."

According to Mr. Malcolm, the Leeds borough coroner, also, there is "a great amount of undiscovered crime in Leeds," but unlike Mr. Herford, he draws the conclusion that the circumstances which encourage it lead also to the holding of a large number of *unnecessary* inquests. In 1881 he himself passed no fewer than 189 deaths which had not been certified by medical men, and in the first part of 1882 he had passed in the same way 88 such cases. "*If certificates in such cases were given the jury would not have to be summoned, nor the expense incurred.*"

Here we have two highly responsible public servants commenting on the same acknowledged abuse, but in an exactly opposite manner; the one contending that inquests are held too unfrequently, the other that they are too numerous; both, however, agree in assuming that crime is encouraged by the custom which leads to an offence or to a desirable consummation, according to the point of view from which each regards it. It is perhaps something in the way of explanation to know that neither of the coroners referred to is a member of the medical profession, so that it would be unfair to expect them to appreciate the full importance of the facts on which they dwell. Mr. Malcolm, indeed, hurls well-merited censure on the employment of unqualified assistants, and rightly insists that "if people would only employ qualified medical men, and pay cash for their services, such cases would not arise, because a proper certificate of death would always be forthcoming." But then this proceeding on the part of the people is just that which it would be unreasonable to expect so long as the universal authority on all matters medical, the General Council, regards the sins of unqualified practitioners and those who abet them, with the vicious leniency it so persistently exhibits; and it will be vain for any voice to raise itself in condemnation of the grievous injury done to the public and the profession by quacks and pretenders of all descriptions, so long as the Council pursues its present course of masterly inactivity.

The question now to be considered, however, is of too great importance to be relegated to other hands than those of the profession as a whole; and in one way or other it must receive the attention it demands, and be settled on a basis that shall rescue it from the palsied grasp of incompetent legislators. When two independent officials feel urged to speak on a subject they are fully capable to register an opinion upon, in terms so decisive as those ascribed to the coroners of Leeds and Manchester, we need no further testimony to the vital interests involved in its complete discussion. Unless they had ample reason to feel convinced of the truth of their suspicions, they would not, we may be assured, have ventured on the plan they have adopted to give them publicity; and it becomes a matter of more than local importance to sift the evidence on which these convictions are founded, and to adopt defensive measures against the spread of an evil which threatens the foundations of civilised life. Unfortunately, the subject is surrounded with other complications than those already mentioned. The holding of

inquests is a delicate matter in those places where, as happens in most non-metropolitan districts, the emoluments of coroners are dependent on the number of inquiries over which they preside; and in connection with this aspect of it will have to be considered the protests raised by independent witnesses against needless investigations ordered with a view to the distribution of fees. We cannot now discuss this side of the question, although there is at this moment before us a communication which refers directly to it; what presses at once for solution is the problem how far crime is cloaked and assisted by the method of granting and withholding certificates of death adopted in this country. It will be noticed that Mr. Herford regards the *giving* of certificates as the *fons et origo mali*, while Mr. Malcolm ascribes the same influence to their being *withheld*. The former asserts that medical men grant a certificate in cases concerning which they can have no reliable information to guide their diagnosis; the latter, that because doubtful deaths are not certified, because they have not occurred subsequently to attendance by a duly qualified medical practitioner, that therefore they are of necessity passed by the registrar in spite of being often most unsatisfactorily accounted for. Different, therefore, as the premises of the two coroners are, the conclusion to which they point is the same, viz., that every person who is ill *ought* to be attended by a registered practitioner throughout the duration of illness, and, when death occurs, that it should be formally and conscientiously certified by such practitioner. No one can deny the desirability of such a happy realisation of idealists' dreams, but who can foresee it unless a much more vigorous and able body of guardians is entrusted with the care of medico-legal affairs than has ever yet assumed their control? Whether or not we harbour the gloomy presentiment of ill—and that we must do so is hardly possible to deny—there are still innumerable abuses that call for remedy under any scheme of reform devised for the protection of the public and the better ordering of the medical profession. If crimes are committed, and pass undetected solely because of deficiencies in the mode of registering deaths, it is surely a duty of the Government to assist all earnest endeavours to abate the evil; and though we might be disposed to wish for a closer agreement between the arguments adopted in proof of the charge brought by the two gentlemen who have most recently re-introduced it, we cannot fail to be grateful to them for adding force, by whatever means, to what we have been consistently urging for years. We have shown that the ultimate end is the same, and we cordially wish success to the endeavour now made to bring it more nearly to hand.

THE SCOTCH LICENSING AND IRISH GRINDING TRADES.

THE Report of the evidence given before the Royal Commission on the Medical Acts which has just been issued contains an immense fund of interesting and valuable information upon subjects which are of supreme interest to the profession, but none of the witnesses whose testimony is printed in the report were able to

offer to the Commission evidence so valuable to the cause of medico-educational reform in Ireland as Dr. William Stoker, of Dublin. Dr. Stoker was invited to appear before the Commission as *facile princeps*, the witness who knew best how to dodge an ignorant or idle student through the portals of the profession and to circumvent the efforts of the medico-educational purists who are exercising their ingenuity to keep such persons out of medical practice.

Scores of such *ignorami* have been thus licensed to practise on the unhappy public, and, though it is somewhat late for the discovery, the light thrown upon the Scotch diploma trade and the medical licences of the Irish Apothecaries' Hall is at this juncture invaluable. The courage which Dr. Stoker has shown in coming forward to make a clean breast of these matters and in defying the resultant unpopularity deserves our best thanks and unqualified admiration, and we are glad to have the opportunity of corroborating to the fullest extent every word of those portions of his evidence of which we have any means of judging. In fact, the accuracy of Dr. Stoker's statements is notorious in Ireland, and the only regret we feel in connection with their being made public arises from the fact that Dr. Stoker was not questioned respecting the open sale in Dublin for the last twenty years of certificates of "diligent" attendance on lectures and hospital to students being employed all day long in other business, had never entered the lecture-room or hospital during any moment of the period for which the certificate of "diligent" attendance was granted. The following is as full an abstract of Dr. Stoker's evidence as our space permits us to give:—

Dr. WILLIAM STOKER, of Dublin, examined.

How many pupils have you prepared during last year, 1880?—I can only say that I have prepared over 184. I have 184 names on my book.

Could you from your notes give us any idea of the number that you have prepared for the different examinations in the United Kingdom?—I have taken down a note of 56 that I have prepared for the Royal College of Surgeons in Ireland, 48 for the Queen's University, 32 for the King and Queen's College of Physicians in Ireland, 26 for the Scottish licences, 13 for the Royal College of Surgeons, England, about 5 for the London University, 3 for the London College of Physicians, and I think about 9 for the Apothecaries' Hall in Dublin; and many of those would be repetitions of the names of the 26 prepared for the Scottish licences. I would take them for the Scottish licence, and might send them for the half of the Apothecaries' Hall examination in Dublin.

Why do you send them for the first half to the Apothecaries' Hall in Dublin and the second to the license in Scotland?—For two reasons, expense and easiness of the examination.

Do you think that it is the cheapest and easiest mode of getting a person on the Register for him to go to the Apothecaries' Hall in Ireland for the previous examination, and to pass him for the second part in Scotland?—Easiest, yes; cheapest, no.

Why not the cheapest?—The Queen's University would be cheaper; but it is much cheaper for the Irish student to take the half of the Apothecaries' Hall than it is for him to go over to Edinburgh or Glasgow.

Will you explain what you mean by "facility"?—Easiness of the examination.

A less degree of knowledge, in fact?—Yes. There are two factors in it. The simple one is that the examination is much easier; and the second factor is that a man can utilise his knowledge doubly. The subject considered most important in the examination of the Apothecaries' Hall is *materia medica*. This is there a part of the First Half. In Edinburgh, on the other hand, it forms part of the Final

examination. If, then, a candidate know *materia medica* well, it serves him doubly, balancing weakness in the scientific subjects in Dublin, and in the practical subjects in Edinburgh. I mean the licences of the Scottish corporations as contrasted with the degrees.

Do you think that there is a very marked inequality amongst the various examinations which admit young men to the Medical Register?—A very marked inequality indeed.

You, as a private teacher, make it the study of your life, I presume, to get your pupils through those examinations?—I do. It is my one aim.

What fee would you charge for putting a young man into the London University?—Thirty guineas.

What would be the cheapest rate at which you could prepare a pupil to pass one of the inferior examinations to get his name upon the Register?—Ten guineas. It would be more profitable to pass men for the easier examinations at ten guineas than London University at thirty. I consider the London University examination to be the most difficult, and I think that the Apothecaries' Hall of Dublin is the easiest.

Does the cost very greatly differ?—It does; the cost varies considerably.

Will you give the Commission some information upon that subject?—The cost divides itself into the cost of the diploma fee and the cost of certificates. The diploma fee varies between 16s. and £28. The cost of certificates varies from £45 to £150. By certificates I mean the certificates of attendance on lectures and clinical instruction at hospitals required from candidates by all licensing bodies prior to their admission to examination. This variation in cost results in part from the great differences in curriculum among our licensing bodies, but also from the difference in cost of the same certificate at different schools.

What curriculum would be covered by £45?—That of the Queen's University of Ireland, if taken out at Belfast, Cork, or Galway, would cost about that sum. If the same curriculum were taken out in Dublin it would cost at least twice as much. The Chairs at the Queen's Colleges being endowed by the State, permits of the certificates being issued at much lower fees than is possible in Dublin.

Can you give me any instance of an examination in anatomy which is very cheap, and which is inefficient on account of the attempt to make it cheap by not having a fee to pay for subjects?—I do not think it possible for the Apothecaries' Hall of Dublin to examine men for sixteen shillings.

Is there much variation in the time required by the various licensing bodies in order to obtain degrees?—Very great variation. Some licences are obtainable in a minimum time of two years and five months. In some the Medical Council's suggestions of four years is, I believe, rigidly carried out. The ideal time in most of them is four years. I say "ideal" because in some cases the modes recognised as the commencement of medical work, are so numerous and elastic under slight strain as to be practically valueless.

Would you yourself personally think it a good thing for medical education that that suggestion of the Medical Council with respect to the four years should be carried out?—In some respects, yes, subject to the proviso that means were taken to secure the candidate working for the greater portion of that four years.

You have made it the business of your life—I may say for a good many years—to study the difficulty and the variation of the degrees of difficulty?—His contract with his pupil is to teach him just so much above the standard of the examination he is required to pass as may obviate the possible ill-effects of chance.

If an examiner is a good long time on a Court of Examiners, you make a study of his questions?—I do; and a very close study.

Are there any examiners on the various boards for which you prepare your men nearly all of whose questions you know?—There is one examiner, I think, all of whose questions I know.

You make it a study to try and find out as many of their questions as you can?—I do; that is the great object of my life.

Will you tell us how you set about it?—I closely watch the whole business. I have two things to find out, first the questions and next the answers. As regards the questions I examine the man's previous papers very closely. I

exclude the questions which have recently been asked by this gentleman. I very carefully consider the questions which he has asked for a considerable interval.

You adopt the negative and positive mode in fact of ascertaining the information?—Yes, I could give you cases both ways. You asked me did I know of any case of rapid repetition; and I may say that there is one respected gentleman who happens to be alive, I am glad to say, and his number of questions is something under 50. The students all say 40, but that is not accurate. He repeats those 50 questions; that is to say, he takes a section of those 50 questions from time to time; he does not repeat the previous paper.

Are those written questions or are they generally oral?—I think they include the whole of this gentleman's questions. The written questions are used for *viva voce* at the next examination, and *vice versa*. Examiners have an enormous inclination toward that. If I hear that a man has given *viva voce* at any given place, that *viva voce* is very carefully considered for his next paper. I am pretty sure that in his subsequent examination he starts with a few fresh subjects, and then when he is tired, towards the end of the day, he will have got over his first selection, and he will think of what he will ask, and the probability is that he will drop on to the last examination paper because he has considered it deeply and has brooded over the answers.

Will you now tell us the negative method by which you arrive at it?—The negative is by no means equally applicable. There is one gentleman, an examiner, whose examinations have extended, I think, over 16 years. I have a *précis* of 14 years of his examinations, and the total of his repetitions is under a dozen. I speak in this case of printed papers.

Therefore you exclude those subjects with him?—Yes, certainly, I am perfectly safe in doing so.

Do you yourself personally approve of the professors themselves examining their own pupils, and how do you deal in those cases?—I do not approve of the professors examining their own pupils; such an examination is never a fair one. The members of a professor's class have exceptional opportunities of calculating the questions which are most probable, they further have opportunities of learning the answers which are most probable, they further have opportunities of learning the answers which this professor requires.

What do you think the principal effect of visitation by the Medical Council has been upon your own pupils?—The rejection rate has been much higher at that examination at which the visitation took place.

Has it continued, do you think, to exercise the same influence?—It has not. The next examination was unaltered. The rejection rate is very much higher at the visited examination, and the students all believe the sole reason for that is the increased difficulty in the examination. So much is that true, that a number of men withdrew when even the rumour of a Medical Council visitation reaches the place. If it were known in sufficient time beforehand that such visitation would take place, the class presenting themselves would be enormously reduced.

The visitation, therefore, seems to make the element of chance enter more largely into the examination?—It would be a temporary element of disturbance. I may add that the nervous excitement of the candidate bears a part in this result, they think they will be slaughtered. I am perfectly satisfied that the examiners are not themselves conscious of any change in the mode of examination.

Of your own pupils educated in Ireland do many of them go to Scotland to pass?—Yes, a fair number do.

Do many of them go to Scotland after having been rejected in Ireland?—Yes.

From what body?—From the Queen's University.

Where do they go to?—To Edinburgh.

Do they prefer Edinburgh or Glasgow?—Edinburgh.

Of your own pupils do a large majority of those rejected at the Queen's University go to Edinburgh to pass?—All who do not remain to re-present themselves for examination at the Queen's University.

They do not as a rule try any of the corporations in Ireland?—No, they could not do so.

Why is it that young gentlemen rejected at the Queen's University do not present themselves to our College of Surgeons or to our College of Physicians?—They have not the necessary certificates to do so.

The curriculum of the Queen's University suits them in fact for Edinburgh, but would not suit them for Dublin?—Yes, that is so. The previous examination of the Queen's University is one of those accepted by Edinburgh in lieu of their own previous examination; but the College of Surgeons of Ireland will not accept any previous examination in lieu of their own. Thus a disappointed Queen's University candidate, disappointed either through having presented himself and being rejected, or disappointed from being informed that he has no chance of passing, goes to Edinburgh, where he simply has to pass the final examination of the corporations, he having already passed the previous examination at the Queen's University.

You are aware, are you not, that some corporations require that the candidate before presenting himself shall sign an engagement that he has not been rejected at any place else for three months before?—I am.

Can you tell the Commission how that regulation is evaded?—A candidate, dreading the result of the examination to which he has presented himself, or to which he is about to present himself, would send in an application to the other licensing body to be admitted to examination. He says, "I am in for one examination; I am afraid I shall be rejected, and I now send in an application to another licensing body, which may make this restriction, and I state that I have not been rejected for the past three months by any licensing body."

Do you know of your own personal knowledge of that having occurred?—Yes, clearly.

Is it your experience that by certain portals men pass on to the Register with very imperfect qualifications?—It is my belief.

May I ask if in Dublin it is the practice of the students before presenting themselves for examination to go to yourself, or to some other gentleman acting as you do as a private teacher?—All, save the poorest of them do.

Take the College of Surgeons of Ireland, for instance, would any student present himself without going to a private coach?—Yes, but very few. I would say about one in six or eight.

With regard to the system of candidates passing say the early examination at one board, and then going to a second board for the final examination, do you think that that system is one which leads to much abuse?—I do.

So that a candidate may appear with the diploma of a particular body when he has not gone through the whole series of examinations of that body?—Yes, and he frequently does so.

You look upon a system of that kind as not a good system?—It is open to abuse, but it is a very convenient system.

Are we to understand that one great reason of university students going to Scotland is because the curriculum of the Scottish corporations closely approximates to that of the Queen's Colleges?—Yes.

And that therefore a course of study pursued in the Queen's Colleges fits a man for examination at the Scottish corporations when it does not fit him for examination before the Irish College of Surgeons?—Yes.

And do you look upon this then as one great reason why a number of young men educated in Ireland do go to Scotland?—I hold it to be the reason that disappointed Queen's University candidates go to Scotland. Irish candidates who go to Scotland mainly are made up—First of Belfast students; with them the qualification of the Scottish corporations is often a primary choice. The communications between Belfast and Edinburgh are at least as close as those between Belfast and Dublin. It is easy for a Belfast man, and it costs him less to go and live in Edinburgh for a sufficient time for examination than to come up to Dublin and live there; so that an Edinburgh qualification may be regarded as a home qualification. The second class would be the rejected Queen's University candidates. The third, Queen's University aspirants who are advised not to present themselves for examination. These two last classes go to Edinburgh as a secondary choice. They go because their certificates will not admit them to examination elsewhere. The fourth class are poor Dublin students who cannot afford the extra cost of the Royal College of Surgeons, the certificates required by Edinburgh being much less costly than those required by Dublin.

You have referred to the visitation of examinations by visitors appointed by the General Medical Council, have you any reason to think that the standard of examination has on

the whole been improved by that system of visitation?—I do not know of its being influenced by it permanently.

Excepting at the particular examination at which the visitors happen to be present?—Yes. I believe there is an increased difficulty in the examination at the time of that particular examination. I further believe that that increased difficulty is not so great as the students universally believe it to be.

That is to say the examiners do not purposely make an examination which is being visited more difficult than an ordinary examination.—No, they do not.

THE ASPECT OF PHARMACY.

If for nothing more than the address delivered before it by the President of the year, the nineteenth annual meeting of the Pharmaceutical Conference, held last week at Southampton, must rank high in importance. We were entitled to expect that Professor Attfield would acquit himself in this capacity in a way to ensure attention to the suggestions contained in his address; and now, with it before us, we can confidently congratulate him and the members of the Pharmaceutical Conference on the excellent advice reflected in the Presidential speech. To medical men it is interesting, not only on account of its dealing with a subject intimately allied to the practice of medicine, but also because of the necessary warnings it contains respecting the injurious custom of amateur doctoring fostered by irresponsible trading in secret remedies. Nor is it only "patent" medicines that are thus distributed wholesale to the public, for in numerous instances the vending of drugs is undertaken by persons who cannot by any possibility claim to rank as druggists. Injury is done in this direction, of a two fold kind; firstly through the ignorance of retailers, who cannot, without special education, be judges of the goods they sell; and secondly, by establishing risks of accidental or intentional mischief arising out of administration, by unskilled hands, of poisonous substances thus indiscriminately sold.

The remedy for existing irregularities is unquestionably the one Professor Attfield proposes, and consists in limiting the distribution of drugs to druggists, such druggists being compounders as well as distributors of the drugs with which they deal. And this desirable change will, he concludes, be brought about internally by education, externally by legislation.

Another most salutary improvement foreseen by Prof. Attfield, and as earnestly anticipated by every reformer in the medical profession, is the substitution of open recommendation of simple remedies by pharmacists for the secret preparations which now rule paramount with so large a section of the general public. It is assumed, also, that such simple remedies will be compounded by pharmacists who are themselves manufacturers of the components, and thus able to guarantee their trustworthiness, a proceeding that has been all but banished through the influence exerted by certain "wholesale manufacturing druggists." It is satisfactory to find, however, that Prof. Attfield has been careful to impress on his hearers the necessity for disabusing themselves of the notion that they are to assume the proper functions of the medical adviser, though from the earlier part of his advice this might have presented

itself to them. He insists that improved pharmaceutical education will suffice for the changes he hopes to see inaugurated, and that only. "Let there be no pretence," he continues, "of professional medical treatment mixed up with pharmacy. Let the druggist's recommendation of simple remedies be founded on that knowledge and experience which comes of much pharmaceutical familiarity with remedies, and on that common sense and perception in all that pertains to drugs with which a properly and specially educated pharmacist may be credited." We need not say how cordially we endorse this admirable recommendation; but, much as we may wish to see it adopted, it is not, in our opinion, a wholly certain consequence.

We cannot go over the whole of the ground covered by Prof. Attfield's address. In turn he discussed the collection, preparation, and distribution of drugs; and as well as exposing existing defects, laid down well-considered and excellent suggestions for future amendment. It is not too much to hope, perhaps, that, coming from a source so authoritative and influential, the proposals contained in the address may become something more productive than paper propositions.

Notes on Current Topics.

The Electric Light at the Post Office.

THE vast advantages of the electric light over gas in rooms where large numbers of people are employed at work were incontestably demonstrated last week at the General Post Office, St. Martin's-le-Grand. In the top room of the telegraph department, that large block of buildings on the western side, about 1,200 persons are engaged, the whole of the upper floor being apportioned to them. For a long time the authorities have had in view the desirability of replacing the gas lights by which this important department has been illuminated, with electricity; and at last the improvement has been carried into effect, with most manifest addition to the comfort of the *employees*. The system of lighting adopted is Edison's, and the power is supplied from the offices of the Edison Electric Lighting Co., on Holborn Viaduct, distant from the post office over one-third of a mile. This is a greater length than the light has yet been carried from any one point, and the success attending the experiment has been most gratifying. The large room is supplied with fifty-nine of the lamps familiar to every passenger by night along the Holborn Viaduct, and the marked change in the atmosphere of the apartment since the substitution of them for the gas burners in use up to the present adds very materially to the comfort, as it most undoubtedly must tend to preserve the health, of those who work under it. The light, moreover, is eminently fitted for the purpose of enabling the work done in the room to be effectually carried out, being evenly distributed over the tables, without shadow; and in every way it is a marked improvement.

THE Russian physician, Dr. Yavorski, who was in attendance on the late Ameer Shere Ali, will shortly publish an account of his journey in Central Asia.

The Fever Epidemic at Acorington.

IN consequence of an outbreak of scarlet fever in Acorington, extensive measures have been adopted with a view to checking its spread within the township, the chief of these being compulsory closing of all the schools. This was first ordered to be done about four weeks ago; but, in spite of the precautions thus taken, it was announced at a largely-attended meeting of school managers, held on Friday evening last, that during the week there had been five deaths from scarlet fever and thirty-eight new cases. These figures, unfortunately, exhibit a considerable increase on those for the week preceding, but the type of fever is described as being generally milder than was the case a fortnight since. In view of all the circumstances, however, a decision was arrived at not only to continue to keep the day schools closed, but to apply the same measure to Sunday schools also. This proceeding will commend itself to the thoughtful, and will, it is to be hoped, result in complete banishment of the dreaded disease from the town.

Professor Pasteur's Researches.

A SUM of 50,000 francs has been placed at the disposal of M. Pasteur by the French Minister of Agriculture, with the full approval of the Budget Committee. The money is designed to assist the researches M. Pasteur is conducting on the causes and nature of contagious diseases among animals, and is the third sum granted to him for this purpose. A similar amount was voted in 1880, and 40,000 francs in 1881. The French mind, it would appear, is capable of appreciating the importance of scientific work of this kind, and of encouraging its continuation.

Vaccination Opponents.

AN inquiry has for some days recently been in progress at Norwich on behalf of the Local Government Board respecting the alleged deaths of children through vaccination. Among those who were called in evidence on Friday last was a Mr. Samuel Matthews, described as a "surgeon accoucheur," and who appeared to have seen, in a professional capacity, some of the deceased children. He had "been consulted by about twenty mothers with regard to children who had been vaccinated. About ten or twelve came from the country, and the others from various parts of Norwich. The children were greatly suffering from erysipelas. He was not an advocate of vaccination." After this intelligence, it is not surprising that the information should have been elicited from him that "his name was not on the Medical Register, and he was not qualified to be placed on it." It might be as well for the population of Norwich, perhaps, that a little further investigation should be made by a competent authority into this gentleman's claims to be entitled "surgeon-accoucheur" or to practice in a capacity he manifestly has no right to fill. We shall refer to the inquiry and its result again when it has been finally completed.

A FUND has been opened at the Mansion House by the Lord Mayor on behalf of the sufferers by the famine prevailing in Iceland. Fodder or provisions may be sent to the depôt of the fund, at 134 Southwark Street, and will be as acceptable as money.

The British Association.

THE British Association held its annual meeting for 1882 last week, at Southampton, under the presidency of Mr. C. W. Siemens, F.R.S. The address delivered by Mr. Siemens dealt chiefly with matters of general engineering interest, and especially with the subject of electrical developments. Among the sectional addresses the most important in a medical sense was undoubtedly that of Dr. Arthur Gamgee, in Section D, Biology. Its title is "The Growth of our Knowledge of the Function of Secretion," and commences with a sketch of the writings of the late Professor F. M. Balfour. Dr. Gamgee presents a complete historical view of the subject, but naturally dwells in greatest detail on the researches inaugurated by Johannes Muller and our own Goodair. The conclusions arrived at at the end of the address are mainly to exalt the importance and dignity of the individual cell, the process of secretion appearing to be the result of the combined work of a large number of such units. "Each, after the manner of an independent organism, uses oxygen, forms CO₂, evolves heat, and derives its nutriment from the medium in which it lives, and performs chemical operations of which the results only are imperfectly known to us, and which depend upon the peculiar endowments of the cell protoplasm, of which the causes are hidden from us."

Fluctuations in the Cost of Irish Workhouse Relief.

DURING the past year there has been in Ireland an increase of £28,463 in "out-door relief," an increase of £1,982 in "salaries and rations of officers," and an increase of £21,149 in "all other expenses," making a total increase of £51,594, from which is to be deducted a decrease of £16,212 in "in-maintenance and clothing," and a decrease of £221 in the cost of relief for "deaf, dumb, and blind," being a total decrease of £16,433, leaving a net increase of £35,161.

The Two Societies for the Abolition of Vivisection

HAVE been having a big flare-up at Willis's Rooms. The annual meeting of these combined associations was assembled in a large room capable of accommodating some 100 persons. The worthy chairman waited some considerable time before opening the proceedings to an annual gathering of sixteen. There were present the Rev. Mr. Grove, Mr. Jesse (the energetic and irrepressible secretary), three men, four women, a little girl, and four members of the Press. A report was read, in which it was stated that the financial position of the two societies was flourishing. Reference was made to the fact of the Royal Commission upon Vivisection, the merit of procuring which was claimed for the older society. What work had been done by the one with the vicious title we are not informed. The Rev. Mr. Grove, after proposing his own re-election as President, and that of Mr. Jesse as Hon. Secretary, proceeded to deliver a few remarks, mainly, we understand, on the *lucus a non lucendo* principle. Mr. Grove condescended to express it as his opinion that vivisection had never been productive of any good.

"Nurses" for Soldiers in War.

WE learn that, profiting by experience in the Transvaal and Zululand, the authorities have selected a very strong staff of nurses for the seat of war. Including a contingent from the National Aid Society, twenty-five of these ladies are now under orders, a portion of whom will, we believe, be drafted to Malta and Cyprus to look after the sick and wounded who will arrive there from Egypt, whilst the rest will proceed to the seat of operations. A few will remain on board the *Carthage*, where, we doubt not, their services will be invaluable. The vast utility of the scheme of the National Aid Society, whereby a staff of nurses maintained at its expense were trained in military hospitals, is now evident, as at least seven of the nurses going out are supplied from that source. But a word of warning appears to be necessary on this head. Sentiment is good, provided only it be limited to matters of sentiment. But if, we take into account the material of which the rank and file of our army is composed, there is no reason whatever to anticipate that in the midst of that material the position of "nurses" will be any more appropriate now than it has proved to be on very many previous occasions. Neither do the utmost roughs and realities of war come at all within the sphere of sentiment. It is not at the seat of military operations that ladies are at all likely to be useful. Gallantry alone prevents us from questioning the advisability of their presence there on any grounds whatever. What really is required under such circumstances is a staff of well trained, *elderly*, and experienced soldier-orderlies, by whatever term designated. But, unfortunately, the short service system militates against this very essential requirement, nor can it be expected that any number of "nurses" will compensate for this important drawback.

Workhouse Relief in Ireland.

IN their lately issued report, the Local Government Board for Ireland state that the number of persons who received relief had been increasing in each successive year since 1877, and reached the maximum in the year ended February, 1881, when the average daily number of persons relieved in the workhouses during the year amounted to 53,796, and the average daily number on out-door relief to 60,883; but the Board is now able to report a change in the other direction, the average daily number of workhouse inmates in the last year, ended February, 1882, having been less by 1,024 than in the previous year, and the average daily number on out-door relief having diminished by 687.

IN the year ending the 31st of March, the excise duty on medicine vendors was net £4,688 15s., in addition to the stamp duty on patent medicines of £144,883 9s. 6d.

THE Editor of the *Irish Medical Directory* will feel greatly obliged if those gentlemen who have not yet returned their corrected statement of qualifications, &c., for insertion in the *Directory* for 1883 will do so at once. He also solicits information as to inaccuracies, either of omission or commission, in last year's issue, as, in consequence of the difficulty of eliciting replies, he finds it almost impossible to eliminate all errors.

The Coffee Tavern Movement.

THE Commissioners of Inland Revenue, in their report on the present year, ending in March, 1882, write of the beer duty:—

"The duty on beer, however, fell short of our estimate. This deficiency appears to have been due to a slight falling off in the consumption of beer. This may be accounted for in several ways, but principally, we think, by the improved habits of the people. This movement has been greatly encouraged and promoted by the erection of coffee-taverns; and when we mention that between thirty and forty limited liability companies for carrying on coffee-taverns have been formed in various places during the past year, and that over one hundred new establishments have been opened in the metropolis, some of them on an extensive and expensive scale, it will be seen that the success of such enterprises must sensibly lessen the consumption of alcoholic drinks. The manufacture of temperance drinks has also been exceedingly brisk; and whether from a prevailing demand for such beverages, or from a love of novelty on the part of the public, an unprecedented number of them has been advertised."

This is a report most encouraging to the philanthropist. We would, however, use the occasion to remind temperance organisers that they cannot reasonably hope to induce the average working man to use non-alcoholic drink unless they provide him with something to drink which will not cost him much more than his beer. Looking at temperance from its practical aspect, we know that in accordance with present custom, the working man *must* "stand a drink" in his turn, and must drink something himself when offered it. To do so is a matter of business, and the artisan cannot afford to be eccentric in such an affair; but he cannot be always imbibing zoedone, or any of the rival "dones" at 5d. a drink; nor can he constantly be swilling coffee; so that he finds it exceedingly difficult to interchange bibulous hospitalities without falling back on the inexpensive beer. We should suppose it possible to produce some wholesome, palatable, and clean-looking liquor at a low price, and we advise temperance reformers to make an effort in this direction. It is bad diplomacy to expect the artisan to be too heroic; and whoever devises the best method of enabling him to appear to drink without really imbibing alcoholic liquor will be the most useful common-sense temperance reformer of his day.

The Health of Irish Workhouse Inmates.

THE Irish Poor-law Commissioners report that, in the year just passed a decrease of 6,604 has taken place in the total number admitted to workhouses in sickness, the decrease in the number suffering from fever and other dangerous diseases having been 1,806, but that there was an increase of 2,934 in the number admitted who were not sick. Deaths by fever were 552, as against 758; by lung disease, 2,317, as against 2,323; and deaths by small-pox 64, as against 97 in last year.

DR. H. SLADE, retired fleet surgeon, R.N., committed suicide at Bodmin by severing some of the arteries in his right thigh.

The Multitude of American Diploma Shops.

THE profession in the "old country" is now intent on perfecting a means of dealing with the abuses arising out of the shop competition of nineteen licensing bodies, and, as a part of the project of law which is to set these abuses right, there is also a proposal that all colonial and foreign diplomas are to be registered and admitted as qualifications to practise in this country under certain restrictions.

We should like to know how this is to be done, or how a satisfactory choice is to be made, considering that the number of licensing bodies in the States is now almost incredible. A report of a committee on medical legislation was read before the Medical Society of Pennsylvania at its last meeting, from which it appears that in the State of Pennsylvania alone 6,492 practitioners are registered, besides 500 licensed practitioners who have not sent in their names. There are also registered within the State 838 practitioners who have no licence. These 7,830 persons hold their qualifications from the following number of licensing bodies:—

From the State of Pennsylvania	...	22
From other American States	...	100
From Europe and other foreign countries	...	50

Total diploma-granting bodies ... 172

The bodies whose licences are recognised by the State of Pennsylvania include eight avowedly homœopathic, three "hygeo-therapeutic," and several eclectic colleges, besides a multitude of unknown bodies. It is proposed, we believe, that the General Medical Council shall investigate the educational and examinational requirements of foreign licensing bodies before admitting their *alumni* to practise in Great Britain? May we inquire how it is proposed to proceed to examine into the title of these 172 licensing bodies in case they apply, as many of them assuredly will?

Poisonous Bullets.

M. GROS, of Paris, with regard to the complaints which were made of the use of poisoned bullets, explains that the construction of the modern breech-loading arms causes the bullet to convey with it a portion of the hydrocyanic acid which the explosion of the powder has caused to be accumulated in the barrel. Even if poisoning to a mortal extent does not take place, it is remarked that the healing of wounds is materially retarded by this circumstance.

Proposed Notification of Infectious Diseases in Switzerland.

THE *Times* informs us that the Swiss Parliament has just rejected a project of law which, unfortunately, included compulsory vaccination, "because of its inquisitorial provisions touching the isolation and treatment of patients suffering from infectious diseases."

THE old Carmichael School of Medicine, which adjoins the House of Industry Hospitals, Dublin, and which has been disused since the opening of the new School in Aungier Street, at the south side of the Liffey, has been sold to the Guardians of the North Dublin Union for £2,500, to be refitted as a Dispensary and Workhouse School.

Kolpokleisis for Vesico-Vaginal Fistula.

DR. R. LOMER, of Leipzig, in a reprint from Langenbeck's *Archives*, Bd. xxvii., 3, reports a series of thirteen cases of urinary fistula met with in the clinic at Heidelberg. Two of these cases operated on terminated unfavourably. In the first of the two, after every method of operation had been tried in vain, that of "Episio-plastik" was tried. This was an attempt to close the vaginal orifice by flaps brought from the thigh. The operation was only a partial success, union not being complete. The second was a case in which there was complete absence of vesico-vaginal septum and part of the urethra. The cure in this case was attempted by kolpokleisis, after the formation of a recto-vaginal fistula upon the sphincter ani. After repeated attempts the closure of the vagina was not only not effected but the urine still dribbled away. But what was worse, feces and wind found their way through into the vagina, so that the artificial fistula had to be closed, and the patient was finally fain to depart unrelieved.

Quackery in Germany.

MANY people think they do these things better in Germany—that there a paternal Government, vigilant and strict, takes the greatest care of the interests of all its subjects, and that it keeps a sharp look-out that quacks and mountebanks do not pursue their unholy calling to the prejudice of the health of such good but weakly-minded Germans as would be inclined to employ them, as well as to the legitimists in medicine. Quackery (*Kurpfuscherei*) is not unknown in Germany. If Dr. C. Kanzow, Regierungs and Medizinal Rath, is to be believed, it actually flourishes after a fashion even in such departments as that of Potsdam, under the shadow as it were of the throne. In his last official report, 1882, "Das öffentliche Gesundheitswesen im Regierungsbezirke Potsdam, 1875-1880," he first falls foul of midwives, who, he says, take too much on themselves at confinements, are guilty of provocatio abortus and drunkenness. He then goes on to say that "quackery flourishes, from the male attendant who has overstepped his authority to the village schoolmaster who has to keep a horse and carriage to enable him to attend to his out-door 'homœopathic' practice, every species is represented, and the business is carried on more or less unblushingly, whilst here and there it happens that even a professor of the healing art is engaged as 'Kassenarzt,' or medical officer to an institution or society." If quackery is such a hardy plant that it will grow even in the uncongenial soil of Germany, what wonder that it becomes rank and overgrown in our favourable soil!

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:— Birkenhead 16; Wolverhampton, Brighton, Derby 17; Edinburgh 18; Bristol 19; Plymouth, London, Dublin, Bradford 20; Oldham, Glasgow 21; Blackburn, Preston, Portsmouth 23; Norwich 24; Halifax, Birmingham, Cardiff 25; Manchester, Huddersfield, 26; Liverpool, Sheffield 27; Leicester 28; Newcastle-on-Tyne, Hull, Leeds, Salford, Sunderland 30; Nottingham 33.

German Naturalists and Physicians.

THE 55th Meeting of German Naturalists and Physicians will be held at Eisenach from the 18th to the 21st of September. Besides the general and sectional meetings, there will be *réunions*, and excursions to places of interest in the neighbourhood. On Friday, the 22nd, there will be an excursion to Kissengen, a reception in the Konversationsaal in that place, a breakfast *à la fourchette* with wine, then a visit to the drinking wells. Dinner at 4 o'clock, and in the evening an illumination of the gardens, a *réunion* in the Casino of the Aktienbad, with supper and a ball. As Eisenach was one of the places in which Luther was at school, the interest will naturally be heightened by Lutheran associations, and the Wartburg, hard by, in which the great reformer spent a considerable period in secret and almost compulsory retirement after his departure from the Diet of Augsburg, and which will be one of the places visited, will not fail to add its quota to the interest and enjoyment, scientific and historic, afforded by the meeting of the Association in the good old town of Eisenach—a town that may be said to belong to antiquity: for tradition says that it was a *berühmte stadt* in the time of the *Völkerwanderung*, i.e., in the 4th century, the first incursion of the Huns taking place, as is supposed, in the year 375.

Tickets of membership, or for attendance as sympathisers, for gentleman and lady, cost 12s., and can be procured through Herr Kaufmann Gustav Döbner, Karlsplatz No. 8, to whom applications may also be sent for lodgings not later than Sept. 10th.

The Treatment of Delicate Children.

HOLIDAY colonies and asylums for children are strongly advocated in the *Deutsch. Med. Zeitung* by Dr. Mettenheimer, of Seumerin. By the former he means the "boarding out" of delicate or sickly children in seaside resorts, and by the latter the reception of the same class of children into permanent institutions. As the alternative of boarding out (and to him it appears preferable), he suggests the erection of wooden dormitories that shall serve for the one season only. He cites an example worthy alike of being seconded and followed. His own words are as follows:—"This spring I had the great joy of learning that a family of distinction residing on the Baltic coast had decided to receive two delicate girls, the children of poor parents, for the summer months, and to provide the baths as ordered by the medical attendant. The family who, in this manner, gave so brilliant an example of pure philanthropy, turned to me in confidence with the request that I should point out two such children. I succeeded in finding two children—one, a girl from Mecklenburg, and one from the Prussian province of Saxony, children whose parents could not think of carrying out themselves the bath and air treatment recommended by the medical attendant. May this proceeding on the part of that family which, I am sorry to say, I should not be justified in distinguishing more closely, find many imitators!" What blessings could be dispensed in this manner both from a physical and spiritual point of view! for in no more noble manner can the bond that unites man to man be strengthened.

WE greatly regret to learn that Dr. Moore, of Adee, co. Louth, who gave such valuable evidence before the Select Committee on Irish Poor-law Superannuation, is dangerously ill with typhus fever.

At a meeting of the various public bodies of the town and county of Aberdeen held last week, it was resolved to appoint deputies to appear at the Southampton meeting of the British Association to urge the claims of Aberdeen as the place of meeting for 1884. Oxford is said to be, owing to some unknown cause, unable to carry out arrangements for the meeting which was to be held there in 1883.

OFFICIAL despatches have been received from the Philippine Islands confirming the reported increase of cholera. Hitherto only natives had been attacked, but the deaths of several Europeans are now reported. The Government have adopted most stringent measures regarding vessels arriving from the East. Four thousand natives are said to have died of cholera.

A DEATH under chloroform took place in London last week at University College Hospital. Deceased, a man named Stimson, was placed under its influence for the removal of a cancer of the tongue, and died before the operation. An inquest was held on Saturday, at which it was shown that the usual precautions had been observed, and that, had deceased not died thus, he could only have lived possibly a few days. The jury, adopting this view, cast no blame upon the hospital surgeons, but gave a verdict of "Death by misadventure."

THE annual death-rate per 1,000 from diarrhoea in the large towns which had been equal to 2.4 and 2.7 per 1,000 in the two preceding weeks, further rose to 4.1 last week, but was still below the average for the season; the rate in the several towns ranged upwards from 0.6 both in Derby and Birkenhead, to 9.1 in Preston, 9.6 in Cardiff, and 10.0 in Nottingham. The highest annual rates from whooping-cough were 1.3 in Sunderland and 1.5 in Blackburn; from scarlet fever, 1.2 in Portsmouth and 2.3 in Hull; from measles, 4.4 in Huddersfield; and from fever, 1.1 in Liverpool and Preston, and 1.2 in Portsmouth. Small-pox caused 5 deaths in London and its suburban districts, 3 in Birmingham, one in Wolverhampton, one in Nottingham, and one in Newcastle-upon-Tyne.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE EXTRA-MURAL SCHOOL, EDINBURGH.—Owing to the jealousy felt by the Surgeons' Hall division of the school at the popularity of Minto House, there will be no introductory lecture this year. The honour of opening the session has been eagerly sought after by the junior members of the school, and for years the introductory lecture was attended by one or other of the Presidents of the Colleges. This year the functions of orator for the session fell to Dr. Craig, who unfortunately happened to lecture at Minto House, and this fact alone accounts for the discontinuance of the time-honoured

custom of opening the session. We also learn that Dr. C. Watson Macgillivray is to lecture on "Systematic Surgery" during the ensuing winter session, and rumour also states that he is to take the place of his uncle, Dr. Heron Watson. With the exception of Dr. John Duncan the Extra-Mural School, since the promotion of Mr. Chiens to the Professorship, has become especially weak with regard to the teaching of surgery. Considerable interest is, therefore, felt in the new lecturer, who, however, comes to his task well prepared and fortified by the experience gained in his uncle's class, which he has frequently had to conduct. Dr. Macgillivray is also a candidate for the post of Assistant-surgeon to the Royal Infirmary, for which he appears to be especially fitted.

ABERDEEN UNIVERSITY.—RETIREMENT OF PROFESSOR PIRRIE.—At a meeting of the University Court, held on the 23rd inst.—Dr. Alexander Bain, Lord Rector, presiding—a letter was read from Dr. William Pirrie, Professor of Surgery in Aberdeen University, requesting to be allowed to retire from his chair, on the ground of age and infirmity, and on the provision as to retiring allowance sanctioned by the University Ordinances. The Court agreed to report to the Queen and Council that Dr. Pirrie is, by reason of declining years, incapable of discharging efficiently the duties of his office, and that he ought to be permitted to retire. The Court also agreed to recommend, in the special circumstances, and considering Dr. Pirrie's long and successful services, extending over a period of fifty-two years, that an increase of ordinary retiring allowance should be granted. The Lord Rector, Principal Pirrie, and others present expressed sympathy with the retiring Professor.

THE CHAIR OF SURGERY IN ABERDEEN.—Expectation is rife as to the future successor to Professor Pirrie, and considerable activity is already evinced by the candidates, among whom are mentioned Dr. Alexander Ogston and Dr. Ogilvie Will. Of the two, Dr. Ogston is certainly the best known out of Aberdeen, and in the town itself has, we believe, been for some time suggested as the future successor to the chair of surgery. We know nothing of his capabilities as a lecturer—a point far too frequently ignored in the selection of professors, and which is of considerable importance in a Scotch University where the student is frequently inflicted with five months of attempts to impart knowledge by "vain repetitions" and unutterable stammering. The selection of either candidate will confer honour on this ancient seat of learning.

THE ATTACK ON DR. WHITELAW, OF KIRKINTILLOCH.—Some time ago we reported the brutal and cowardly attack on Dr. William Whitelaw, of Kirkintilloch, who was lured at midnight from his residence by a woman representing that his services were required for an urgent case. On the way he was attacked by the same woman and two men lying in ambush, robbed, and brutally ill-treated, so that his life was despaired of. In connection with this case, a man and woman were apprehended, and after trial they were last week sentenced at Stirling, by Lord Mure, the man to eight years' penal servitude, and the woman to five. We are glad to be able to report that Dr. Whitelaw is rapidly improving, though still unable to use his limbs thoroughly.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 19th inst., the mortality of Edinburgh was 72, and the death-rate 16 per 1,000. Under one year there were 17 deaths, and 13 above 60, of which 1 was above 80. Seven deaths were reported from zymotic causes, 1 measles, 1 whooping cough, 1 diphtheria, 1 typhoid fever, and 3 scarlet fever.

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, the 19th inst., was at the rate of 22 per 1,000 per annum of the population, as compared with 21 per 1,000 for the previous week. For the corresponding weeks in 1881, 1880, and 1879, a death-rate of 20, 23, and 19 was recorded respectively.

Literature.

RINGWORM. (a)

We have here a monograph of 150 pages on a special subject, by one who has had considerable opportunities of observing the disease in question. The reader will, therefore, expect to find a good deal of information about the disease in question—its varieties, diagnosis, prognosis, and treatment. He will not be disappointed. Ringworm of the body is scarcely mentioned, the book being almost entirely devoted to ringworm of the scalp, but of this there is a very complete account. The different appearances it may present are carefully described. The author states that in the scurfy condition of the scalp, often described as following ringworm, the disease is often still present, and, though not receiving specific treatment, may thus be frequently communicated to others. He particularly emphasises the importance in all cases of preventing the spread of the disease, and urges the necessity of a careful medical examination of the scalp before the return of children to school. Were this regularly and efficiently performed, we have no doubt that epidemics of ringworm in schools would become a tradition of the past. Dr. Alder Smith states that he has constantly seen cases in which children have been sent back to a school with a medical certificate, and the disease has, on examination, been found to be still uncured and highly contagious.

In a special treatise it is somewhat disappointing to have no account of the parasite. There are several good illustrations in the plates, but no account of its natural history.

DISEASES OF THE SKIN. (b)

In the present volume we have, within a compass of 800 pages, a concise and readable account of cutaneous affections. The work is, on the whole, well written and fairly up to date. We notice some omissions. We have looked in vain for any account of pellagra, acrodynia, or piedra. Flea-bites, when very numerous, may lead to an erroneous diagnosis, but we do not find any reference to the bites of fleas or any other insects, or of the effects produced by lodgment in the skin of harvest-bugs or the West Indian chigoes.

The chapter on statistics is disappointing. It occupies only seven pages, and consists simply of an enumeration under each disease of the number of patients of either sex who have been under the observation of Dr. Bulkley in private and public practice respectively. The information thus conveyed is certainly not very excessive, and does not fulfil the expectations raised by the sub-title.

In spite of these drawbacks, we can commend the book as a whole. Many useful hints will be found scattered through its pages. The chapter on diet and hygiene is especially good. Under ringworm, the author very properly refers to the benefit sometimes derived from the internal administration of tonics in addition to local treatment. He adds a caution as to the use of sulphurous acid, viz., that it should be fresh, as the sulphuric acid formed by oxidation is useless to destroy the parasite, and only irritating to the skin. We are glad to see a mention of the use of iodoform internally in the later affections of syphilis.

An Anonymous Donation to Stratford-on-Avon.—At the annual meeting of the Governors of the Stratford-on-Avon Infirmary on Monday, the senior physician, Dr. Kingsley, announced a donation of £6,000, and a site for the proposed new building, the bequest of a gentleman whose name was not divulged.

Sir Erasmus Wilson's Munificent Gift to Margate.—At a meeting of the Governors of the Margate Royal Sea Bathing Infirmary on Monday, Sir Erasmus Wilson, F.R.S., handed over the key of the magnificent new wing of the infirmary, to be named the Erasmus Wilson wing, which he has built at an estimated cost of over £30,000. The wing includes two large day-rooms and four dormitories, each to contain sixteen beds, with a swimming-bath capable of containing 15,000 gallons of sea water.

(a) "Ringworm: its Diagnosis and Treatment." By Alder Smith, M.B. Lond., F.R.C.S. Second Edition. London: H. K. Lewis. 1882.

Correspondence.

SEA-SIDE CAUTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your recent leaderette with the above title has caused in me a mixed feeling of agreement and disagreement with your views. Your second and third injunctions as to sea-bathing, viz. not to remain in the water long enough to feel numbed, and to take a brisk walk immediately after dressing, seem unexceptional; but I beg leave to doubt the wisdom, as a general practice, of your first rule, viz., to take some light refreshment before bathing.

I am not referring to invalids, or to those women weakened in their nerve power in varied functions and parts, by, e.g., the strain which bearing a large family often induces, or to women of middle age, who have had, in shops, &c., a long life of indoor and foul air depressing influences; but I refer to the average type of English people of the middle class, from six years of age to forty. My very strong impression is that such, when they go to the seaside in July or August, should rise at 6 a.m., walk in a cheerful mood to the beach or rocks, and plunge in whilst warm from the walk on an empty stomach.

I seem to see good reason, in women, for example, who suffer the neuroses of epigastric sinking, or spasms, or headache, taking a small cup of good coffee or tea before they go out for such an early walk and dip; indeed, I believe such stimulant would enable a very great number of women who, when at the seaside, injuriously spend the glorious morning hours in bed, to rise and to spend two hours in bathing and exercise, and to their own immense good. But if you mean by "refreshment" anything approaching even a light meal, I should venture to differ from you.

Viewed theoretically, if food be taken into the stomach, the nerve "energy" of the system must be diverted to that organ, and to the "work" thus there imposed on it. Of course, I am aware that certain states, such, e.g., as the epigastric sinking which some suffer from in the middle of the night, may be relieved by a mere crib of biscuit or crust just as effectually as by a *lot* of some stimulating drink; but I assume that a drop of tea or coffee at 6 a.m. does not draw vital "energy" to the stomach in particular in the same way as food would do.

We desire that the bather plunges into the water whilst yet in a glow, and with vigorous circulation. I think this end is likely to be promoted by the hot drink, and to be retarded by the food.

But theoretical ground, Sir, is very slippery! Will you allow me, therefore, to state my experience, which is to the effect that for persons of average health, from eight years of age to forty, the early morning sea-bath, *on an empty stomach*, and carrying out your second and third rules, is a most safe and commendable habit. In an English climate the habit must be practised in the summer months only. I have never any fear of children bathing in the sea on gloomy or wet days, provided always that they have a place in which to keep their clothes perfectly dry; and I should be most particular in the case of females that the bathing dress be not only dry, but "thoroughly aired," even if within sixty seconds after, the bather will be as wet as a "header" can make her!

During some years past I have induced a great number of somewhat delicate young people (girls mostly), from ten years upwards, to bathe in the sea before breakfast. I have never heard of injury in any case. I have always been under the impression that after a night's sleep the conservative vital "energy" of the body is at its highest; on awakening, our best ideas and thoughts return unbidden; some of the organic vital functions, e.g., the sexual, are in high state of polarity. The labourer who lives in a natural mode of life goes to his two hours' work without inconvenience, and I believe that a mighty good, and no danger, would accrue to the British Philistines who crowd our most frequented watering-places if they "turned out" at 6 a.m., and after a brisk walk, went through some active exertion in the sea, followed, as you suggest, by a brisk walk. Two hours of such practice on an empty stomach before breakfast would restore the vigour and health of the great army of British Philistines of both sexes. To some of us who have travelled much, and seen Biddy from Cork do her four hours' washing before breakfast, or seen the Bengalee boatmen paddle their dingy from 4 a.m. to 10 a.m. without tasting food, taking only an occasional draw of the hooka (pipe), or seen the labourers in the Demerara sugar-patch

work for hours before breakfast, &c., it is to us a very humiliating contrast to view the pampered follies which increasingly grow up among respectable people of this country?

I must venture to differ from you also, on the dangers of wettings from salt water. I have been some thirty times around the world, in the latitudes south of Capes Good Hope and Horn, in charge of thousands of people: I do not think that I ever saw illness caused by drenchings in sea-water. Personally, I became indifferent to being drenched by the great seas breaking over the ship: sometimes I would change clothing, but as a general rule, I would not take that trouble, but remain wet and re-wetted. The top of a mighty wave would come on board and drench a crowd of people. I never myself took cold, and this same immunity extended almost as fully to the people.

As illustrating the seemingly slight circumstances on which health and disease depend, I may mention that, having always worn American cotton twill trousers, and being in Madras when the heat was great, I ordered a stock of brown holland trousers, as being cooler. I tried them over and over again, but always suffered in consequence—chills, or diarrhoea, or aching in the limbs. So marked and curious did this seem, that I used to speculate whether or not the linen texture had some special conducting power of the hypothetical vital conservative "energy" of the body! Be this as it may, of the facts of the danger of linen, and the safety of cotton, I was forced to believe, as I was also of the absolute safety of a wetting from sea-water, and of the great danger of a wetting from a mere shower in Bengal or Guiana.

These reminiscences may be of value practically, or suggestive of the exquisite delicacy of those physical and vitophysical correlations which the living body has with Existences, and on which its normal states, or health, and its deviated states, or diseases, depend. Pray pardon any seeming dogmatism in the tone of this letter. Those of us who strain our powers for more light will always feel, when groping with the most seemingly simple phenomena of the organic world, the infinite depth of the wisdom of the poet—

"There are more things in heaven and earth, Horatio,
Than are dreamt of in your philosophy."

Yours truly,

Plymouth.

WILLIAM H. PEARSE, M.D.

CONSULTANTS AND PROFESSIONAL ETIQUETTE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I would thank you to let me know what you think of the conduct of a consultant whose behaviour was as follows:—

I was in attendance on a lady residing within a quarter of a mile of me, and in my district; and the case being an anxious one, the friends naturally desired a consultation. Dr. A—, of D—, was accordingly called in. I met him, and we agreed as to the nature of the case and its treatment. A second consultation was arranged for the following day, and we met again, with similar results. I continued to attend my patient regularly twice a day afterwards; and in about a week after our last meeting I was informed that Dr. A— had visited my patient, independently of me, on two separate occasions, on one of which occasions he altered the treatment. As I write I receive a letter from Dr. A—, informing me that he saw the patient last evening, and prescribed for her, and asking me to meet him this evening in consultation.

This seems to me to be a most extraordinary course for a consultant to pursue; and, indeed, I look upon his conduct as a violation of all professional etiquette.

I am, dear Sir, yours faithfully,

RICHARD CRONIN, M.D., &c.,

Dist. Med. Officer.

Conyngham Lodge, Slane, Co. Meath.

19th August, 1882.

P.S.—I should mention that Dr. A— lives at a distance of seven miles from the patient's house.—R. C.

[If A—, being a consultant, visited the patient without letting the medical attendant know of his intention to do so, or of his having done so, he acted very improperly in our judgment. It may be, however, that being in the patient's neighbourhood he paid a running visit, which

might be excused. If he visited and received fees as a medical adviser when he had been called only as a consultant, he was guilty of a serious breach of etiquette.—
Ed. M. P. & C.]

SUPERVISION IN LUNATIC ASYLUMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I hope you will excuse me if I make a few comments on your editorial remarks respecting the case of sudden death at the Waterford Asylum. I quite agree with you that the case should have been more thoroughly sifted, for the cause of all such accidents in asylums should be placed beyond doubt; but how "the presence of other eyes within the asylum besides those of the administrative officers" could have prevented such an accident I am at a loss to know. In Waterford Asylum, as in every other in Ireland, there is a visiting physician attending daily. What assistance was he in this case? The *Medical Press* occasionally, when advocating the necessity for visiting physicians in asylums, has endeavoured to make little of the resident medical officers. To my mind visiting physicians as consultants, when required, are most useful, but as daily visitors to satisfy the public that "other eyes besides those of the administrative officers are within the asylum," they are not only useless, but a needless expense. I do not question that as a matter of comfort it is better for a superintendent to have a daily visiting physician. All responsibility is thus divided, and no one officer is responsible; but for the efficient working of an asylum, an assistant medical officer is far more needed. Post-mortem examinations should be more frequently held. I have no doubt patients are now not infrequently buried with undiscovered injuries. In English asylums, where post-mortem examinations are the rule, fractured ribs and other injuries never suspected during life are often found.

Yours truly,
M.B.

August 10th, 1882.

Obituary.

JOHN PATERSON, M.A., M.R.C.S.

MR. JOHN PATERSON, one of the oldest members of the profession in Aberdeen, passed away on August 24th, at the ripe age of 85 years. Deceased was born and educated in Aberdeen. He had always shown himself courageous and sympathetic in the discharge of his duty. Evidence of the possession of these qualities, as well as of his ability, was given by Mr. Paterson many years ago, when cholera was making sad havoc among the fishing communities along the coast to the eastward of Aberdeen, as well as in the Footdee district. He laboured incessantly for many weeks at that period, his cheery manner and his warm-hearted kindness doing much to sustain the spirit alike of those who were suffering and of their relatives. As a result of his labours during the epidemic, he published his "Observations on Cholera: its Non-Contagious and Non-Infectious Qualities," besides contributing largely on the subject to the Government reports of the period. He also wrote a pamphlet on "The Principles and Practice of Midwifery, and on Flooding after Labour," betokening at once his great knowledge of that subject and his literary skill. In the city he has been Medical Officer of the Dispensary and of the Oldmachar Parochial Board, and his services to the poor were rendered in no grudging spirit. Mr. Paterson was greatly esteemed, and those who knew him best loved him most.

PASS LISTS.

University of London.—The following candidates have just passed the Intermediate Examination in Medicine for Honours (Anatomy):—

<i>First Class.</i>	
Anderson, G. E. C. (Exhibition and Gold Medal), Guy's Hosp.	Innes, C. B. (Gold Medal), St. Bart's Hosp.
<i>Second Class.</i>	
Robinson, H. B., St. Thomas's Hosp.	Brock, J. H. E., University College.
<i>Third Class.</i>	
Flannery, P., University Coll.	Watson, W. I. B., Guy's Hosp.
Carr, J. W., University Coll.	Cooper, H. C. E., Guy's Hosp.

The following passed the Materia Medica and Pharmaceutical Chemistry Examination:—

<i>First Class.</i>	
Carr, J. W. (Exhibition and Gold Medal), University College.	Innes, C. B., St. Bart's Hosp.
	Woolbert, H. R., University Coll.
	Flannery, P., University Coll.
<i>Second Class.</i>	
Whitcombe, F. P., St. Mary's Hospital.	
<i>Third Class.</i>	
Brock, J. H. E., University Coll.	Hayman, W. S., King's Coll.
	Randell, E. M. H., Guy's Hosp.

The following passed the Organic Chemistry Examination:—

<i>First Class.</i>	
Innes, C. B. (Exhibition and Gold Medal), St. Bart's Hosp.	(a) Dutt, U. K., B.Sc., St. Mary's Hosp.
(a) Spoug, C. S., B.Sc., Guy's Hosp.	Anderson, G. E. C., Guy's Hosp.
<i>Second Class.</i>	
Elliott, J., B.Sc., Owens Coll.	Brock, J. H. E., University Coll.

The following passed in Physiology and Histology:—

<i>Third Class.</i>	
Anderson, G. E. C., Guy's Hosp.	Cooper, H. C. E., Guy's Hosp.
Tratman, F., Bristol Medical School.	Randell, E. M. H., Guy's Hosp.
Vernon, J. V. D., Guy's Hosp.	Spoug, C. S., Guy's Hospital.
	Bowes, W. H., Guy's Hospital.

N.B.—The bracket denotes equality of merit.

(a) Obtained the number of marks qualifying for a Medal.

University of Aberdeen.—The following candidates having passed the required Examinations, have just received the Degrees of this University:—

Doctors of Medicine

Ackroyd, George Streatham.	Macdonald, Coll. B., Beith.
Atherstone, Edwin, London.	Macdonald, William Inverness.

(c) Received highest Academic Honours.

(d) Honourably distinguished.

At the same time the following were certified as having passed all the examinations, but did not graduate:—

Brown, Henry Herbert.	Leslie, John Tasman Waddell.
Hudson, Francis Joseph.	

Notices to Correspondents.

DR. E. C. E. (Gruyere, Switzerland) will please receive our thanks.

DR. McK. (Stonehaven).—Thanks for the promise.

DR. J. E. S. (Liverpool).—We have perused the local papers sent us, and cannot see that any other verdict could have been arrived at. You were clearly in the wrong, and we regret you did not seek the advice of a disinterested party before going to law.

MR. E. W. TOWN (Derby).—Thanks; the Report would be of little interest to our readers; do not trouble to send it.

A CONSTANT READER (Rathmines).—The French Pharmacopœia gives no formula for "cucumber ointment." For "pommade de concombres," which will probably answer your purpose, the formula is: Axonge, 1,00 grammes; graisse de veau purif., 600 grammes; baume de tolu, 2 grammes; eau distillée (de rose), 10 grammes; suc de concombres, 1,200 grammes.

DR. A. T. THOMSON (Glasgow).—Case received; shall appear in an early number.

A. H. (Edinburgh).—His qualifications were correctly described.

A SUBSCRIBER (Perth).—Two of the three ruffians who attacked Dr. Whitelaw were arrested, and their sentence passed at Stirling last week; the third escaped. You will find reference to this case in our present issue under the head of "Scotland."

DR. S. (Manchester).—Owing to your letter being addressed to a member of the staff personally it was delayed, in consequence of the absence of that gentleman. Kindly address "The Editor" in future in all matters relating to the Journal, thus avoiding delay.

A NOVEL METHOD OF SUICIDE.—An inquest was held on Saturday last at St. Bartholomew's Hospital on the body of a man named Hussey. Deceased had left his wife in consequence of disagreements and suspicions, and had gone as far as the steps of the Hospital, where he filled his mouth with gunpowder and set a light thereto with a match in "the hope of blowing his head off." The procedure was not immediately effectual, but he died soon after being taken into the Hospital, where a jury subsequently passed a verdict of "suicide whilst of unsound mind."

L. M. C.—A curious illustration to the same effect is contained in several of the older works on obstetrics. It may fairly be questioned how far reliance is to be placed on them, however, and it would be decidedly unwise to repose any confidence in the course they recommend on emergency. Consult the last edition of Gant's Surgery for a description of the operation.

DR. JOHNSON (Kilkenny).—The information you seek is contained in a shilling pamphlet published two or three years since by Messrs. Baillière, Tindall, and Cox, entitled "The Mineral Waters of Contrexeville," by Dr. Tamin-Despalles. A map is attached of the route.

MR. G. M. (Falmouth).—Sorry we are unable to accede to your request; it is contrary to our rule; consult any respectable practitioner in your town.

A SUBSCRIBER (Reading).—The death reported in the *British Medical Journal* of August 12th was an error. Mr. Jeston, of Henley, is still living, and we understand, in excellent health.

COMPLAINANT.—The holding of such frequent and unnecessary inquests is to be deplored both from a ratepayer's point of view and the pardonable sentiment associated with the feelings of relatives; but we fear, in the present state of the law, the coroner to whom you refer has not exceeded his legal rights, albeit some of the inquiries smack of "the gold that glitters."

MR. J. HATTON (Coleford).—Will reply to your inquiry in our next.

LUNATIC.—Your letter was inserted and replied to in the Irish Supplement of our last issue.

DR. J. ROGERS will please receive our best thanks.

DR. MURRAY.—From the description you give, we imagine you refer to "Ingluvin." Although a somewhat extravagant value may have been assigned to it, it is undoubtedly sometimes very useful in obstinate cases of sickness; and in the vomiting of pregnancy it has certainly, in our experience, proved useful. We would suggest, as likely to be beneficial to your patient, the malt extract jelly manufactured by Messrs. Brand and Co., by the employment of which, in a somewhat similar case, we recently obtained satisfactory results.

MR. MASON.—The operation is a plastic one, and would hardly be suitable under the circumstances.

H. R. B.—There are many instances on record, and most works on jurisprudence contain several allusions to such monstrosities. It is impossible at present to explain their occurrence, and, as a theory, yours is probably as good as most attempts to account for them. On various grounds, however, it falls short of the full requirements, and we cannot advise you to bring it before the world.

DR. M. S. (Ballycroy), asks:—1. If a ticket issued to one member of a family residing in my dispensary district is cancelled, am I bound to attend that member or any of same family residing in same house on a red or black ticket? 2. If a ticket issued to one member of a family is cancelled, does that include the other members of same family, residing in same house, or am I bound to attend the other members of same family where one of them has been cancelled on a red or black ticket? 3. If a warden issues a ticket for a cancelled person, together with a note stating that the person for whom he has issued ticket is in poor circumstances—although the members of the Dispensary Committee who cancelled the ticket did not consider that person in poor circumstances—am I bound to attend on it? 4. Can I claim my fee of the issuer of a ticket, he knowing it to be cancelled?

[1. If a ticket be cancelled, you need not attend that ticket, but must do so if a new ticket be granted to same person until the new ticket has also been cancelled. 2. The cancelling of a ticket for one individual of a family does not, of course, cancel those tickets granted to others of same family. 3. You must attend on a ticket, no matter to whom it is issued. 4. If a ticket is issued to a person whom the issuer knows not to be a suitable recipient, you may sue him for the fees, and will recover them.—ED.]

CERTIFYING DANGEROUS LUNATICS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly let me know in "Answers to Correspondents" in your next issue of the *Medical Press* how I am to act under the following circumstances:—

A dangerous lunatic residing in the dispensary district of which I am medical officer is brought before two justices of the peace, who call in the aid of a neighbouring dispensary doctor and sign the neces-

sary certificates for committal, quite ignoring my services altogether, at the same time filling up in the blank spaces for particulars that the doctor who examined the lunatic was medical officer of the district in which the lunatic resided, mentioning the name of the district.

Now, as I am the only doctor of the district, I wish to know if I can take any steps to recover the fees I should be legally entitled to, or to prevent a repetition of the injustice? An answer in your next will much oblige.

Yours truly,
SUBSCRIBER.

[You cannot, of course, recover any fee, but the transaction is altogether illegal, and, if you lay the circumstances before the L.G.B. they will probably disallow the payment and prevent a repetition of the transaction.—ED.]

MR. STONE'S RETIREMENT FROM THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly allow me through the medium of the *Medical Press and Circular* to express my best thanks for the very kind letters I am daily receiving from all parts of the country consequent on my retirement from the Royal College of Surgeons, and to state that I will answer them all as soon as possible.

I have also to request that all letters of official nature may be addressed to "The Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.," from whom they will receive every attention.

Felham Road, Wimbledon,
August 20, 1882.

T. M. STONE.

Vacancies.

Bristol Royal Infirmary.—House Physician. Salary, £100, with apartments, &c. Applications to be addressed to the Secretary on or before Sept. 7th.

Chichester Infirmary.—House Surgeon and Secretary. Salary, £100, with board and lodging. Applications to be sent to the Secretary on or before Sept. 9th.

Dore Union.—Medical Officer. Salary, £70, and £17 as Medical Officer of Health for the same district. Applications to be sent to the Clerk on or before Sept. 6th.

Downpatrick Union, Portlerry Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 20th.

Mitchelstown Union, Kildorrery Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 15th.

Northleach Union.—Medical Officer. Salary, £57 10s., with the usual extra fees. Also Medical Officer of Health. Salary, £100. Applications to be sent to the Clerk not later than Sept. 12th.

Appointments.

ANDERSON, J. W., M.D., C.M.Glas., F.F.P.S., Dispensary Physician to the Royal Infirmary, Glasgow.

BLACK, D. C., M.D.Glas., L.R.C.S.Ed., Extra Dispensary Physician to the Glasgow Royal Infirmary.

BROCK, W. J., M.B., C.M.Ed., Extra Dispensary Physician to the Glasgow Royal Infirmary.

COSGRAVE, E. M.D., L.R.C.Q.C.P.I., Physician to Simpson's Hospital Dublin.

DOUGALL, J., M.D., C.M.Glas., F.F.P.S., Dispensary Physician to the Royal Infirmary, Glasgow.

EDWARDS, O., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Locomotor District and the Workhouse of the Union.

FRASER, B. M.D., F.R.C.P.Ed., Medical Officer for the North and Central Districts of the Darlington Union.

HOLLIES, G., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Southern District of the Wellington Union, Salop.

MANSON, R. T., L.R.C.P.Ed., Medical Officer for the West and North-West Districts of the Darlington Union.

MIDDLEMISS, G., L.R.C.P.Ed., Medical Officer for the South and East Districts of the Darlington Union.

SHAW, W. J., M.B., C.M.Glas., Extra Dispensary Surgeon to the Glasgow Royal Infirmary.

Births.

O'DONNELL.—August 18, at 30 Darlington Street, Wigan, the wife of W. O'Donnell, L.R.C.S.I., of a daughter.

Deaths.

BANNISTER.—August 22, at Great Malvern, Alfred James Bannister, M.D., of 11 Addison Terrace, Notting Hill, aged 48.

DEAN.—August 14, at his residence, Butler Street, Oldham, Octavia Dean, M.R.C.S., aged 48.

EARLE.—August 15, at Haroda, Bombay, Joseph Herbert Earle, Surgeon, Indian Medical Department, aged 28.

GARDNER.—August 22, at Bungay, Suffolk, James Gardner, M.R.C.S., M.R.C.P. Edin., aged 66.

JOHNSON.—August 17, Richard Locke Johnson, M.D., M.R.C.S., of Bury Place, Bloomsbury Square, London.

MOREHEAD.—August 24, very suddenly, at Wilton Castle, Redcar, Charles Morehead, M.D., F.R.C.P., late Bombay Medical Service, aged 75.

PAUL.—August 18, at Torriano Cottages, Camden Road, N.W., Andrew Paul, A.B., M.B., Trin. Coll. Dub., aged 79.

ROBERTSON.—August 25th, at 28 Albany Street, Edinburgh, William Robertson, M.D., F.R.S.E., aged 64.

TIOBHURST.—August 25th, at Lewes, Sussex, Surgeon-Major Tiohburst, late Bombay Medical Department, aged 60.

NOTES ON THE TREATMENT OF ABSCESS IN BONE.

By HENRY MORRIS, M.A., F.R.C.S.,
Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital.

In 1787, John Hunter, after stating that abscess in bone may find its way to the surface, added, "the crown of the trephine is often necessary in order to get at the seat of abscess." It would thus appear that trephining or drilling for circumscribed abscess in bone was practised by the great master in surgery more than a century ago. It is, however, only since the publication of Sir Benjamin Brodie's paper in the "Medico-Chirurgical Transactions" (1832), just fifty years ago, that the operation has become the almost universally approved treatment of this affection.

It is indeed the only proper treatment; and probably the differences of opinion respecting it nowadays, are confined to the rarity or frequency of the cases which require it, and to the degree of risk attending it. Possibly there are still surgeons who consider, as the late Professor Syme did, that the disease is a very rare one in surgical practice, and that the operation is attended with grave danger. The following six cases, which have occurred in my practice during the last two and half years, point, however, to an opposite conclusion; and seem to indicate that abscess in bone occurs more frequently than is generally supposed; whilst, as regards the consequences of the operation, my personal experience, up to this period, has led me to think that good alone results therefrom in properly recognised cases.

CASE I. Chronic Abscess and Central Necrosis in the Outer Condyle of the Humerus.—Sigismund H., æt. 44, a courier, was admitted on November 17, 1879. Twenty-five years ago he contracted syphilis. For nine years he had suffered from facial rheumatism and facial neuralgia. About ten months ago he had suffered pain in the right shoulder, and pain and stiffness in the right elbow. The

pain in the elbow he described as being "like a pressure of several hundredweight upon the bone." The lower end of the humerus had been enlarged for four months, and for five months he had been unable to straighten his forearm. No treatment had given him any relief.

On admission, there was enlargement of the condylar end of the humerus, especially of the outer condyle; and pressure at one spot on the outer condyle excited pain. He complained of always suffering, but of having frequent paroxysms of great pain, which he described as taking the course of the musculo-spiral nerve to the shoulder.

I propose to trephine the bone at the tender spot, but this he refused until December 10th, when he returned, requesting that the operation should be done. The periosteum, which was greatly thickened, was peeled aside, and the outer condyle pierced with a small drill without result; but, on enlarging the opening thus made with a gouge, a small sequestrum was exposed, surrounded by a few drops of pus. The cavity was large enough to admit the end of the finger; its walls were hard and smooth, but the bone between the cavity and the joint was somewhat softer than natural.

From this time the pain ceased, and on December 20th, he left the hospital before the wound had healed, being able to extend his forearm beyond an angle of 120 deg. After four or five weeks more the wound closed, and he has remained well since.

I saw him on June 25th, 1882, when he described himself as "never better in his life," and he could use his arm quite well; flexion, pronation, and supination were perfect, and extension could be carried to the extent of 148 degrees.

CASE II. Abscess in the Upper End of the Shaft of the Tibia: Fibrous Ankylosis, with Displacement of the Knee.—Francis R., æt. 35, a man of good physique, but having the aspect of much suffering, was admitted in July, 1881. He was deeply pitted with small-pox; had never had syphilis. Seventeen years before admission he struck his right knee against the rung of a ladder, and this injury led to stiffening of the knee and swelling of the bone below the joint. For five or six years an open wound existed over the upper third of the tibia; then it

closed, to break out again and again. At length it finally healed; but throughout the whole of the time since the accident he had suffered pain, sometimes worse than at others, in the tibia. During the last six weeks walking had greatly aggravated the pain.

On admission the right knee was fixed, and the tibia displaced slightly backwards and outwards. The right tibia was much thickened in the upper part of its shaft. The skin over the enlarged bone was natural, except for a supple thin cicatrix. There was tenderness on firm pressure over all the thickened part of the bone, and even slight pressure on one spot gave rise to pain. Of late the pain in the bone had been continuous, allowing him no sleep by night and no rest by day. Many remedies had been tried and failed. I believed there was an abscess in the tibia, and therefore, on August 5th, cut down upon it, and drilled the bone deeply in two places without evacuating pus. The periosteum was much thickened, and the bone was tough and dense. Relief was immediate and complete, and continued for two months; but on October 28th, 1881, about one month after discharge, he returned to the hospital, suffering all the old pains as severely as ever. On November 2nd, I therefore made another incision down to the bone, cutting along the cicatrix of the former wound. There was no difficulty in detecting the places where the drill had been previously introduced; they were filled with soft and ossifying granulations. Along one of these a gouge was worked, and when it had been pushed a little further into the bone than the drill had gone, about three drachms of foetid pus escaped. A steady recovery followed, on December 20th the wound had quite closed, and on January 3rd, 1882, he left the hospital quite well, though his knee was, of course, still stiff. I last saw him on March 1st, 1882, in perfect health, and I should have heard from him had his leg not remained sound and painless.

CASE III. Central Necrosis and Abscess in Lower End of Tibia.—Ferdinand L., *set.* 8, injured his left leg by slipping his foot between some railings. A week afterwards the bone was swollen just above the ankle, and painful enough to keep him awake at night. After four months' treatment without benefit, he was admitted in January, 1882, with uniform expansion of the lower end of the diaphysis, slight redness and heat of the skin over the swelling, and some tenderness on pressure. The fibula was unaffected, and the movements of the ankle were painless and free. He suffered little or no pain after admission, but in about three weeks the soft parts became very red, cedematous, and tender, so that on February 24 I made an incision over the front of the tibia, and peeled back the periosteum, which was a good deal thickened, and partially detached from the bone. Pus at once oozed through a small aperture in the expanded bone, and on enlarging this, between two and three drachms of fluid pus, some inspissated pus, and a small piece of necrosed bone were removed. The cavity was lined by a smooth vascular membrane, which was scraped away. There was but little hæmorrhage. He made an excellent recovery, and in the beginning of May he left the hospital, wearing a temporary steel support for the leg. He has continued well since.

CASE IV. Central Necrosis of Right Fibula: Chronic Abscess in Lower End of Left Femur, giving rise to Suppuration around the Knee.—Joseph B., a fairly healthy-looking lad, was admitted first on October 19th, 1880, when six years old. His family history was good, but he had some slightly enlarged glands in the neck.

About Christmas, 1879, he complained of pain in the right ankle, which became more and more severe, and extended up the leg. Considerable swelling followed in the upper and outer part of the right leg. He limped in walking. Three months before admission, a small piece of bone came away through an opening which had formed over the right fibula. Three weeks before admission, after a fall on his knees, he felt pain in the

lower part of his left thigh, and a little swelling formed above the left knee.

On admission, there was a sinus over the upper third of the shaft of the right fibula leading to necrosed bone, and a day or two after admission a long slender central sequestrum was removed from the fibula. The wound healed rapidly.

On November 27th, between two and three ounces of serous fluid were removed from the swelling over the left femur. It was clearly bursal, and the bursa did not refill. After the removal of the fluid, the lower end of the shaft of the femur was felt to be much expanded. On February 4th the boy was discharged quite well, except that the lower end of the femur was painlessly enlarged.

For eleven months he remained well, but on the 10th of January, 1882, he was re-admitted with extensive suppuration around the lower end of the left femur, and in the popliteal space. All the parts about the left knee were exceedingly tender, and any movement of the knee made the child scream. The joint itself was not, however, affected. On the following day two incisions were made, one above the inner condyle of the femur, and the other at the lower part of the popliteal space, and several ounces of matter were let out. The lower end of the femur could now be felt greatly enlarged. After this, the temperature, which had been 102° , fell to 98.2° , and did not rise above 99° till January 21st; then it rose again, and was frequently as high as 101.6° . The pulse was rapid, the appetite declined, and pain and tenderness about the lower end of the femur and over the knee became very acute. These symptoms, supervening upon a long-standing enlargement of the femur, led me to the opinion that a chronic abscess or central necrosis in the lower part of the femoral diaphysis was the cause of all the mischief. Accordingly, on February 2nd, I made an incision down upon the front of the femur—which was rough as well as expanded—and then peeled off the thickened periosteum with the rest of the soft tissues. A very small opening leading into the interior of the bone was thus exposed, and enlarged by means of a gouge. After going through a considerable thickness of dense, tough, but not very hard bone, an abscess-cavity, as large as a walnut, was laid open, and about half an ounce of laudable pus escaped. More pus was mopped out with pieces of absorbent wool, and the walls of the cavity were well scraped. The patient made a good recovery, lost all pain from the day of the operation, and was discharged well and with a movable knee on May 9th, 1882. There was one inch and a quarter of lengthening of the left limb, due solely to increase in the growth of the femur. The boy remains quite well up to the present time.

CASE V. Abscess in the Lower End of the Tibia.—On February 28th, 1882, Arthur F., *set.* 10, an active and well grown boy, was brought to me on account of a circumscribed swelling of the left tibia, about one inch above the ankle-joint. It came on after jumping from a height, between two and three months before I saw him. The swelling was slowly but steadily increasing. Pain—which for a long time had not been great, and had only been felt at all after walking or standing a good deal—had latterly occurred in paroxysms severe enough to cause him to cry, and keep him awake at night. The attacks of pain sometimes continued many hours, and would then pass off for a week or more. There was tenderness on pressure over the whole of the inner surface of the swelling, but more acute at one spot than elsewhere. I recommended the use of the trephine at the most tender point, and, on March 7th, I removed an egg-spoonful of cheesy-looking semifluid pus from the interior of the lower part of the shaft. After the operation there was no return of the old pain. Within three weeks he was well enough to return home; and I saw him, perfectly recovered, on July 13th.

CASE VI. Central Necrosis of Astragalus.—Frances S., æt. 12, a delicate-looking girl, was admitted on December 18th, 1881. Twelve months before admission, swelling appeared on the outer side of the ankle. Pain, most severe at night, preceded the swelling by some months. Gradually the whole ankle-joint became soft and swollen, like an ordinary white swelling of the ankle. Tenderness on pressure was most marked over the lower end of the fibula. A plaster-of-Paris splint was worn till March 21st, 1882, when she returned to the hospital, feeling no better. In less than a month after removing the plaster-of-Paris, and whilst the limb was still kept fixed, the ankle-joint showed undoubted signs of suppuration; the temperature rose, and rigors set in. On April 17th, an incision was therefore made in front of the inner, and another behind and below the outer, malleolus. On introducing the finger into the outer wound, I felt a small movable fragment of rough bone close to the articular facet for the outer malleolus. This was lodged in a cavity in the astragalus, which was large enough, after the removal of the fragment, to receive the tip of the finger, and was limited by perfectly smooth and uniformly hard walls. The joint was washed out with a solution of tincture of iodine, the wounds covered with terebene and oil on lint, and the limb immovably fixed on a splint. Subsequently the terebene was changed for iodoform, which was dusted over the weak exuberant granulations which had formed. The limb was still kept immovably fixed. No pain has been suffered since the operation; the joint has resumed almost its natural shape, and the wounds are all but cicatrised. I look forward to the patient recovering with a slightly movable joint.

REMARKS.—The operation which was performed in these cases was not, strictly speaking, trephining. In two of them, after dividing the periosteum by a linear incision, and peeling it off for a certain distance, pus was seen to ooze up through a small opening in the bone; and the abscess-cavity was opened up by applying the gouge to this spot.

In three other cases, after dividing and peeling off the periosteum in the same way, a drill was first introduced, and then the drill-hole was enlarged with the gouge. It is not always sufficient to use a drill under the impression that, if a cavity be reached, pus will escape from it along the side of the drill, or through the hole made by it, after its removal; for, as Case I. shows, a little pus with a fragment of necrosed bone may occupy a cavity, but not declare itself by welling up; or the pus may be only semifluid, and too thick to flow, as in Case V. Under either of these conditions, the use of the gouge is needed to expose the abscess.

After emptying it of its contents, the walls of the cavity were in each case well scraped, or rubbed with dry lint, or a fragment of sponge; it was then washed out with iodine solution; and absorbent cotton-wool, or lint soaked in terebene and oil (1 part to 6), was introduced.

In all the cases the limb was immovably fixed in splints; and the subsequent treatment consisted in irrigating the cavity with iodine solution (tincture of iodine, four drachms to the pint of warm water) daily, or every second or third day, according to the amount of discharge; and the application of the terebene and oil on lint.

The situation of the abscess in Case I. was on the epiphysal portion of the humerus, though all the epiphyses had years before become consolidated with the rest of the bone. In the next four cases, one or the other extremity of the diaphysis of a long bone was the seat of disease, though in only one of them was the neighbouring epiphysis consolidated with the shaft. In Case VI. the abscess-cavity was in an irregular, not a long bone. Though this is unusual, it is by no means unique. I have seen the os calcis similarly affected; Mr. Annandale has reported a case in which the lower jaw was the seat of a chronic circumscribed abscess;

and most surgeons have seen the mastoid bone similarly affected from extension of disease from the middle or external ear.

In the case in which the epiphysal end of the humerus was affected, the elbow had become contracted, and the bone between the abscess and the articulating surface was softening down. In all probability, the elbow-joint itself would soon have been disorganised. In three cases in which the ends of the diaphyses were affected, the joints were not involved; but in two of them (Cases III. and IV.) the abscesses, after remaining chronic for some months, took on a more acute form, and led to inflammation of the surrounding soft tissues. In Case IV. it produced extensive suppuration in them, and fistulae were beginning to form; whilst, in Case III., diffused abscess in the leg would certainly have occurred had the disease not been cut short by operation.

It is interesting to note that in both these cases (Cases III. and IV.) little or no pain was suffered for a time prior to the soft parts being affected. This was probably owing to the breaking down, in the course of the disease, of the solid inflammatory products which had for a time limited the abscess. These products, by filling the natural spaces of bone, cause considerable intra-osseous pressure, and excite the severe, dull, and continuous pain which is a usual symptom of chronic abscess in bone.

In Case VI., in which the astragalus was the seat of the disease, the ankle-joint became early involved, and thus in great part, if not entirely, the symptoms of circumscribed bone-abscess, or central necrosis, were marked; at any rate, the cause of the suppuration of the ankle-joint was not suspected until actually ascertained. It no doubt was an exceptional case, for the great majority of chronic bone abscesses are in the long bones. But even in them more is seen, in hospital practice, of cases where the abscess has been overlooked or neglected, and has gone on to extensive disorganisation of the bone which it involves, or of the joint in nearest proximity to it, than of cases in which the abscess, still circumscribed within narrow limits, is the only cause of suffering.

To avoid the very serious sequelæ of this affection, as well as to give relief to the distressing pain which it occasions, the diagnosis of bone-abscess and central necrosis is a matter of great importance. I make no distinction between the cases in which pus alone, and pus with a small sequestrum, is contained in the cavity, because there is an identity in the processes resulting in the formation of such sequestra, and in those producing small sloughs of connective tissue in the acute circumscribed inflammations of soft parts.

The diagnosis, it must be confessed, is often very difficult; chronic periostitis, chronic osteitis, and cysts and solid tumours of bone, need to be distinguished from abscess in bone. Periosteal thickenings more commonly affect the middle parts of the shafts of long bones, and are generally amenable to local medicinal treatment; whereas chronic abscess in bone generally attacks the ends of the diaphyses or the epiphyses, and is not in the least benefited by remedies.

Cysts in bone will be rightly treated by being laid open in the same way as a chronic abscess; and chronic osteitis, of the form which gives rise to severe continuous or neuralgic pain (*the ostéite à forme névralgique* of the French), will be relieved or cured by the use of the trephine; whilst the solid tumours require amputation or excision.

Thus, though an accurate diagnosis is admittedly difficult, if not impossible, in some cases, the possibility of falling into error, in spite of careful deliberation, should not discourage us from making an exploratory operation in doubtful cases of disease of bone.

Indeed, I would venture to say that if we made it a rule to trephine or drill in all cases of chronic enlargement of bone, attended with continuous or paroxysmal pain, and which rest and remedies have failed to cure,

we should have the satisfaction of saving life itself in some instances, and of restoring to ease and usefulness the limb in very many others.

AMPUTATION OF SCROTUM FOR ELEPHANTIASIS ARABUM—EMPLOYMENT OF MACDONOGH'S CLAMP—COMPLETE RECOVERY.

By G. V. MACDONOGH, M.D., D.L.H., R.N.

JUST ten years have elapsed since I visited Apia (the capital of Upolu, one of the Islands of the Samoan group, South Pacific), in H.M.S. *Cossack*, of which ship I was then Fleet Surgeon. Shortly after my arrival, Dr. G. A. Turner, medical missionary belonging to the London Missionary Society, and who had been living at Apia for over four years, called on me and requested that I should visit, professionally with him, the wife of one of his fellow missionaries who was living in one of the islands detached from Upolu, somewhere about twelve miles from Apia. Owing to the distance, I had to remain all night at the mission house and whilst wandering about in company with Dr. Turner, our conversation turned on elephantiasis arabum, a disease very prevalent all over this group of islands; he then proposed that we should visit a native who, I think, was either a native teacher, or had been a servant in the employment of the missionaries for a number of years; this person bore an excellent character, and was much loved and respected by his employers.

Dr. Turner told me that the patient had been the subject of elephantiasis arabum for about thirty years, the disease affecting the scrotum had increased enormously and had rendered him quite incapable of moving about and thereby interfered with the earning of his bread. On visiting him I found him seated on the floor, his legs wide apart, covered from his waist downwards with tappa, or native cloth. As it was nearly dark, I could not see well, but he appeared to me to be about sixty years of age, tall and thin, his features bore the expression of long continued suffering, he was not able to speak English, but Dr. Turner acted as interpreter. On removing the tappa a huge black mass was disclosed, having more the appearance of a turtle of some eighty or ninety pounds weight than of anything else I could call to mind, this occupied the space between his legs, extending from the pubes to his feet. When he stood up it rested on the ground. No trace of the penis was to be seen, but a small orifice occupied the centre of this mass from which he passed his urine, it had somewhat the appearance of the umbilicus in a large fat abdomen; he complained only of the weight and of inconvenience to locomotion. On making pressure over the tumour, I was able to discover the position of the testicles, and to ascertain their size from the peculiar sensation communicated to the patient on pressing the organs; they appeared to be about four inches in length by about two and a half in breadth each, in fact, about the size of a large goose egg. Dr. Turner asked me if I thought it would be safe to amputate the tumour, to which I replied that I feared the man being so old and his strength apparently so reduced it would be very hazardous to do so, the loss of blood would in all probability be very excessive, as no doubt the vessels would be considerably enlarged, and there was no way of controlling the bleeding. Next morning, however, before my departure, I again visited the man with Dr. Turner, but I could see very little hope of being able to remove the tumour without involving such risk of his life as, perhaps, would not be justifiable. Dr. Turner explained this to the man, who was exceedingly anxious to have the tumour removed, and he in reply stated that he was quite prepared to incur all the risks, that life was almost insupportable, in fact, he begged and prayed that we would remove it, however, we left him without determining on anything. On my way back to my ship my thoughts were fully occupied with the poor fellow's case, and it occurred to me that I might devise a clamp to place on the pedicle of the

tumour, and on my arriving on board, I talked the matter over with the chief engineer of the ship, Mr. W. D. Benton, described to him what I wanted done and gave him the measurements, thickness and breadth of the pedicle, he very kindly had the clump made for me. It consisted of two parallel bars of iron; attached to the under bar were two upright male screws, one close to each extremity, these passed through holes in the upper bar and brass thumb-screws were then fitted on.

The accompanying rough sketch will serve to make it better understood.

When completed, I showed it to Mr. Horner, the surgeon of the ship, my assistant, and to Dr. Turner, both of them considered that it was fully capable of controlling the bleeding and well adapted for its purpose. Unfortunately we could find no one who was capable of making tourniquet pads to attach to the bars, so we contented ourselves with wrapping strips of washleather around them. The man was brought in to Apia, he was laid on an ordinary kitchen table in an outhouse belonging to Dr. Turner, a couple of turns of a bandage were taken to a hook in the ceiling, by which means the tumour was kept well elevated for a period of about twenty-four hours previous to operating, his buttocks were brought well to the edge of the table. Chloroform was administered to him and when he was well under its influence the tumour was lowered and supported on a plank which was held by two assistants. The clamp had been previously placed in position. Having first fully satisfied ourselves that there was no hernia present, it was tightly screwed down and incisions were made along the lines previously marked out with ink showing the size and form of the flaps that were to serve as covering for the penis, as I had determined to save that organ if possible, but the man was so old and the testicles so enlarged, we thought it better to remove them, plenty of skin was preserved and dissected up from the surface of the tumour on each side of the penis, as also a small piece inferior to the orifice from whence issued the urine. These were turned back and the posterior surface of the penis dissected out of the body of the mass, cross pieces of skin were also preserved to form a covering for the stump superiorly, then a clean sweep was made, dividing both spermatic cords, which were found very much enlarged, and oedematous, the cremaster was very pale and appeared to have lost its contractile power, as there was no contraction of the cords when divided. Before dividing them, however, a whipcord ligature, which had been previously soaked in carbolic acid and oil, 1 to 5, was passed round them and tied. When cut, the spermatic artery was found to be larger in circumference than the radial, right and left cords were treated alike, all bleeding vessels were tied (of which there were thirty), the screws of the clamp were eased up, but the clamp itself was retained in position lest any secondary hæmorrhage should ensue. The flaps were brought together with silver wire sutures over which was placed lint wet with carbolic acid and water, 1 to 20, and over that again was placed more lint saturated with carbolic acid and oil, 1 to 5. The patient was then moved on to a bed, his buttocks resting on a quantity of finely teased oakum well up between the legs, and another mass was also placed in front so that the entire of the wounded parts were well covered by it. In this state I left him under the care of Dr. Turner as the ship proceeded to sea a few days after the operation.

The tumour, when quite empty of blood, weighed seventy-five pounds.

Three days after the foregoing case I operated on another man, also a native Samoan, but belonging to another island. The tumour which he had was very much smaller, it was not half the size of the other, he was apparently a very much younger man than the other patient, and of much healthier appearance. He could himself define accurately the size of each testicle, which appeared to be about the natural dimensions. The same steps were taken in this case as those which had been adopted in the former, except that both testicles were preserved, being found healthy. A very good scrotum was provided for them; the after treatment was exactly the same as in the former case. The tumour when weighed was found to be twenty-two pounds. It bore the marks of having had portions of it excised by a native surgeon some years previously.

I have been given to understand that the native medicine man makes an agreement with his patient that if he survives the operation he is to receive for his fee so many acres of land, having upon them so many bread-fruit trees, bananas, &c., but should the patient die before the fifth day from the date of the operation, it is open to the friends of the deceased to take the life of the operator. The operation is, I believe, conducted in the following manner. The patient and surgeon retire into the forest, a hole is dug, in which the patient lies down, a slice is then removed from the tumour by the surgeon with a semi-blunt instrument, usually a shell, no effort is made to restrain the bleeding. The patient faints from the loss of blood. The operator clears out and returns in twenty-four hours or so, if his patient is alive he gives him some food, and after a little assists him home. When the wound is quite healed and some time has elapsed the same hideous process is gone through again. If the man is dead the surgeon takes care to put the sea between himself and the friends of the victim until such time as their anger has blown over.

In the pamphlet published by Dr. Turner he says that possibly I got the hint of the clamp from the earlier editions of Dr. Druitt's "Vade Mecum," in answer to that I have only to state that the only edition of that book that I ever possessed or read, and I am not aware that I ever saw any other, is the eighth edition, and in that I can discover no mention of any clamp whatever in connection with the removal of the scrotum on account of elephantiasis arabum. Again, he states that I witnessed the late Dr. O'Farrell, of Dublin, remove a similar tumour whilst a student in Dublin in 1844. It so happens that in that year I was living with my brother in Swords, county Dublin, my first session as a medical student was the one which commenced in November, 1845, so I could not have been present at the operation, though, of course, I had heard and read of it as it caused some stir in Dublin at the time. It is quite possible that in the course of conversation I may have mentioned Dr. O'Farrell's operation to Dr. Turner, and he concludes that I must have been present. In the year 1844 I was but sixteen years of age. Again, Dr. Turner states that the tumours were kept elevated for about an hour before the operation; whereas, in my notes written shortly after the operation I find that I have written down that they were kept elevated for twenty-four hours previous to the operation, as stated in my account of these cases. Again he states that in the second of my cases only the right testicle was preserved, and on my referring to my notes I find that I have written down that both testicles were saved to the man, being found natural in size, and healthy; and again I find a discrepancy between Dr. Turner's published statement, and my notes, as regards the weights of the two tumours I removed; the first and larger one he gives as weighing 77 lbs., and the second as 30 lbs. I find that I noted them down respectively 75 lbs. and 22 lbs. However, these are not of much importance, but I do claim the entire credit of the invention of the clamp, and must in the most emphatic way repel the insinuation thrown out by Dr. Turner when he says, "I subsequently found that the

employment of such a clamp is advised in the earlier editions of Dr. Druitt's 'Vade Mecum,' and possibly Dr. MacDonogh got the hint from that source." Except the assistance I received from Mr. W. D. Beaton, chief engineer of H.M.S. *Cossack*, who kindly had the instrument made for me, I received no suggestion from any one or from the written works of any person, notwithstanding the mention that is made of a clamp in the ninth edition of Dr. Druitt's "Vade Mecum," which up to the present moment I have never seen, and only know of its existence by the quotation made in Dr. Turner's pamphlet, page 9. In fact, whatever merits or demerits it may possess, I claim to be the sole author of the clamp used in my two operations.

In a letter received from Dr. Turner, dated 20th June, 1882, he makes the following statement which, I think, shows the very loose way in which his report is made out. One would at least expect accuracy when the cases of another are reported:—"I had the impression that in your second case one of the testicles was removed, but no doubt my memory has confused that case with one of my own ones." But perhaps this inaccuracy may be accounted for by another of his statements in his letter to me of the 22nd of June, 1882, in which he says, "I found that your name had dropped out of the Medical Directory, and I reluctantly came to the conclusion that you were dead." In neither of my cases had I any difficulty in finding either the penis or testicles; as to the testicles, in all the cases I have seen, the patients themselves were perfectly cognisant of their position in the tumour, and could distinctly mark out their outline. It would have been very interesting to have learned from Dr. Turner if, in those in which the testicles were preserved, virility returned.

It gave me much pleasure to learn from Dr. Turner that in both my cases there were such good recoveries, and that my clamp and example enabled him to mitigate so much suffering amongst the poor afflicted natives of the Samoan group, and I hope and trust now that 138 cases have been operated on, out of which number only two deaths have occurred, and even these cannot be ascribed to the operation, it will be frequently performed and made the means of assuaging the sufferings of thousands. This reflection is my reward.

ON TWO EPIDEMICS OF THE PLAGUE AT KHORASSAN. (a)

By Dr. J. D. THOLOZAN.

It is a fact little appreciated by science that most pandemics have commenced at first by isolated manifestations. From this point of view, the slight outbreaks of plague which have prevailed for some time at intervals in the East are deserving of attention.

In 1870 the plague of Vettianka took place in the Government of Astrakan, the exotic origin of which has not been proved. In 1881 an epidemic of serious bubonic fever was observed in Mesopotamia, a region well known as a centre of disease. This was the sixth attack in fourteen years. Three villages in the north-east of Prussia suffered from one of those slight epidemics, the origin of which is not explained by contagion, as we understand it at the present day. It seems to me worthy of interest to give an account to the Academy of this exceptional fact, Khorassan being cited nowadays as being one of the regions refractory to the plague.

The Canton of Djovein lies at twenty-five kilos to the north of the town of Sebzavar, on the route from Teheran to Méched. It is a spacious and fertile valley of twelve to fifteen kilos, by 110 to 120 kilos, situated between two chains of mountains running from east to west. Its altitude varies from 900 to 1,500 metres. Djovein is cold in winter, and warm in summer. It consists of seventy villages, inhabited by 5,000 families.

(a) Communicated to the Academy of Science.

This population is almost entirely engaged in agriculture and the rearing of sheep. The habitations, which are situated on the plain, or on the slopes of the mountains, do not present any conditions generally recognised as favouring the development of pestilential maladies, and their hygienic state does not differ from that of other districts in the province of Khorassan, which is one of the healthiest parts of Persia. In three villages in this country at Djouloumbran in 1878, and at Bondagabad and Kélate-Arab in 1881, an epidemic prevailed which presented some of the most characteristic and gravest features of the black plague. In the month of January, 1878, the chief of the telegraph department at Sebzevar transmitted to Teheran the following news:—"A strange malady appeared in December, 1877, in the small village of Djouloumbran, a place situated in the mountains to the north of Sebzevar. The sanitary condition was not exceptional; thirty-seven deaths had taken place out of 300 inhabitants. The disease commenced with cephalalgia, pain in the side, cough, followed by bloody expectoration, both taking place on the first or second day, with complete preservation of intelligence up to the last moment. The sanitary medical officer of Sebzevar, sent by my advice to this locality in the month of June last, recognised this epidemic, at the end of 1877, as the plague. Glandular enlargement in the armpits and in the groin were observed a certain number of times. The inhabitants questioned on the invasion of 1877 say, that in the memory of the oldest inhabitant such a disease had never been noticed amongst them or in their neighbourhood. They called it *breast pang*, with *bubo*. Since the end of December, 1877—the date of the extinction of this disease—up to the present, not a single case has been observed at Djouloumbran."

The second outbreak to which I wish to draw attention took place in two villages, near one another, situated in the plain at twenty four kilometres from Djouloumbran, and forty-two kilometres north of Sebzevar. The first news of it reached Teheran on the 17th May last. In several houses in the two villages all the inhabitants died. The first village attacked, Bendagabad, had lost at this date more than half its inhabitants. In the second village, Kélate-Arab, 112 out of 1,000 had been carried off; only seven recovered.

The history of this epidemic shows that at first there was a serious disease, with pulmonary localisation, death taking place in twenty-four or forty-eight hours. Later on axillary and inguinal buboes appeared, either with pulmonary symptoms, or with petechial continued fever in the form of typhus. No similar affection had been observed in the memory of man in these two villages. Contagion from without does not explain its origin. On the 25th June the malady had totally disappeared; its cessation is explained rather by the dispersion of the inhabitants than by attenuation of the morbid poison itself. On the 20th of July the inhabitants of Bendagabad and of Kélate-Arab had not returned to their homes; nine of them were sheltered at Sebzevar. From their account the disease commenced, on the 17th of April, in a young woman with symptoms of serious adynamic pneumonia, death taking place in thirty-six hours. On the day after the father and uncle of this patient had the same symptoms; they died in twenty-four hours. Then the malady appeared in neighbouring houses, and there were thirty-five cases and thirty-four deaths out of sixty inhabitants. In consequence of the immediate dispersion of the terror-stricken inhabitants, the disease only lasted five days at Bondagabad. Buboes were not observed in any of the inhabitants of this village. The disease was carried from Bendagabad to Kélate-Arab, on the 25th of April, by the physician who had charge of the patients. He returned to his home already attacked by the contagion, and he died in forty-eight hours of a disease presenting all the features of that at Bondagabad. Three days after the death of the physician his nephew, his brother,

and his sister fell ill, dying in two days. On the 5th of May the epidemic reigned with intensity at Kélate-Arab. On the 10th axillary and inguinal buboes appeared on almost all the sufferers. At the end of the epidemic, June 25, 240 deaths had taken place out of 1,000 inhabitants.

Before the invasion of this epidemic, typhus, or some analogous continued fever, was observed in the infected localities and their environs. Up to the end of June this fever prevailed with varying intensity in the neighbouring towns, Sebzevar, Damghan, Semnan. No bubonic fever—grave or slight—was observed in these localities; no village near Bondagabad or Kélate-Arab suffered from the plague. I may note that those who fled from the pestiferous localities were not received in neighbouring villages, but their clothing was in neighbouring places, in spite of the sent to severe prophylactic instructions sent from Teheran. The orders given for the destruction of the tainted villages by inundation or fire were only imperfectly carried out. Some houses had been burnt; disinfection of a simple nature was carried out in some of the houses.

On the 29th of August all the inhabitants returned to their homes; not a single suspected case was observed up to November 25th. At this date there existed at Sebzevar and its environs some sporadic cases of typhus. Bovine pest (contagious typhus of horned cattle) prevailed near Sebzevar two months after the pneumobubonic plague above described.

Clinical Records.

NOTES FROM PRIVATE PRACTICE.

Empyema—Recovery.

By JAMES WIGMORE, M.D., Q.U.I.,
Twerton-on-Avon, Bath.

ON February 17th, 1882, I was sent for to see A. F., æt. 13, residing in the country about three miles from my house, when I obtained the following history:—

Began to feel unwell on Feb. 16th, about middle of day; got a severe wetting coming from coal-pit a few days before. First felt pain in left side, was sick, and brought up a large worm, did not notice any rigors, and was very well in the morning; feels very thirsty; no appetite; bowels confined. Pulse, 120; temp., 102°. On examination dullness over base of left lung at back, slight tubular respiration, no crepitus, puerile respiration at apex in front. Ordered beef-tea and milk and expectorant mixture.

Feb. 18th.—Pulse, 132; re.p., 48; temp., 103.8°. Sputa rusty, pain less, tongue furred, great thirst. The temperature, pulse, and respiration continued about the same till the tenth day, when they fell to—pulse, 114; temp., 99.8°; resp., 38. On the seventh day there was slight herpes on left lip; pain in side continues very severe. As the temperature again rose to 101°, I suspected some complication, and as he seemed very prostrate, with a dry tongue and red at tip, he was ordered quina sulph., gr. ij., tinct. ferri mur., ℥xv., every four hours. He continued on till March 8th, seeming a little better one day, the next worse.

On March 8th the pain in left side was so severe, he was ordered liq. opii sed., ℥v., to be repeated if necessary.

9th.—The note taken was—slept a good deal, cough troublesome, upper part of left lung tympanitic, dullness commences about third rib in front, apex beat of heart displaced to right side.

19th.—Had a consultation with Dr. Cole, of Bath, when the apex beat of heart was under right nipple; measurement of both sides of chest equal; vocal fremitus present on both sides; pain very severe on touching back of chest. Left side somewhat duller than right; still there was not the absolute dullness one expects to get in such cases. We both agreed to aspirate.

21st.—Tapped chest with aspirator and drew off 8 oz. of pus. As the aspirator became plugged we saw there was no use in repeating the operation, so we decided to open

the chest and introduce a drainage-tube. A few days after I opened the chest between the fifth and sixth ribs, when more than a pint of pus came away, and inserted a Chassaignac drainage-tube, only one opening being made, as recommended in Bryant's "Surgery," vol. ii., p. 61. Air entered very freely through the opening, but it escaped as freely. The following day I found there was a good deal of discharge through the tube. The tube continued discharging till April 10th, when it became blocked; so I washed out the cavity with a solution of resorcin, 3ss. to Oj. of water. A good deal of discharge came away. I repeated the washing frequently, and the discharge, after a few times, became much thinner and less in quantity. About this time, also, I discovered there was a drain at back of house open, which I had closed; and his sister was also laid up with pneumonia, but got all right in the usual course.

April 18th.—The heart was about mid-sternum, and some tubular breathing might be heard over a great part of left side.

23rd.—Sat up in bed for a short time.

May 2nd.—Tube came away, and the wound was closed before my arrival next day. The percussion sound was clear along back.

11th.—Wound in side recommenced discharging—about 5vj. of pus came away. Put in a drainage-tube and washed out cavity as before for the few days following.

17th.—Wound ceased discharging, and tube came out.

21st.—Sat up in bed for an hour. Wound quite healed up. Appetite good.

June 1st.—Walked down stairs, and after that he progressed favourably.

Remarks.—It will be noticed that in this case a great many of the symptoms we are taught to expect in empyema were absent; in fact, the only diagnostic points about the case were the displacement of the apex beat of the heart and the tympanitic condition of the upper part of the lung. Though the left side of the chest was full of pus, still the vocal fremitus was not entirely lost, neither was the left side absolutely dull, nor were the intercostal spaces bulging, and the measurement of both sides was equal. Pain was a very prominent symptom throughout, and the back of the chest was extremely tender. The change in the character of the discharge after washing out the cavity a few times with the solution of resorcin was very marked. It might also be remarked, that though exposure to wet was a marked cause in this case, there was no such history in the sister's case, and there was a case of some obscure form of fever next door, which seemed to improve on having the drains looked to.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TRAUMATIC TETANUS.—At a meeting of the Société de Chirurgie M. Chauvel read a communication on traumatic tetanus which gave rise to a discussion as to the rôle attributed to the great sympathetic in the affection. A soldier wounded himself severely in the left leg, and being put in a prison which was cold and damp, tetanic spasms set in which refused to be influenced by morphia or chloral (six drachms in the twenty-four hours) or chloroform inhalations. Death supervened forty-eight hours after the first symptoms were observed, and the autopsy showed, besides congestion of the coverings of the spinal cord and the brain ecchymosis of the superior cervical ganglion of the great sympathetic, together with general swelling of the nerve which presented a rosy hue. The author was inclined to think that these phenomena had something to do with the tetanus. M. Després thought that nerve stretching which gave such satisfactory results in other affections should be employed more frequently in tetanus. M. Marchant, on the contrary, believed that nerve stretching was absolutely useless. In a case of his he severed the sciatic nerve, but the patient died in spite of all. M. Verneuil was entirely of the opinion of the last speaker;

surgical treatment had completely failed in this affection. He depended more on chloral, with or without morphia, and, above all, complete immobility. In the case of a wound in the hand he had stretched the median and cubital nerves: there was an abatement in the spasms; but he also gave chloral, and the patient got well. He believed he was saying right and giving the opinion of most of his colleagues when he said that chloral is the only medicine that has succeeded in tetanus.

PNEUMONIA IN CHILDREN.—M. Jules Simon, of the Enfants Malades Hospital, gives the following distinctive characters of pneumonia and pleurisy in children:—Pneumonia commences by a rigor, by vomiting, convulsions, and a violent fever. There is no pain in the side; the respiration is quickened, sometimes reaching 60 in the minute. There is a sort of tickling sensation in the throat, which makes the little patient cough incessantly, a little dry cough. During the first forty-eight hours the physical signs furnished by auscultation and percussion are *nil*, or nearly so. The only thing auscultation discovers in the first two days is the absence of the respiratory murmur, and apnoea more or less pronounced. In pleurisy, on the other hand, there is no violent fever, no vomiting, no convulsions; so that often acute pleurisy remains entirely unsuspected by the parents. They take the malady for a simple cold, and at the end of seven or eight days the child is taken up. It is thus parents bring their children to the consulting-room, little imagining the existence of a pleural effusion. However, there is a sign that is not observed in pneumonia, and that is, pain which is not situated beneath the breast, as in the adult, but from some inexplicable cause, in the flank of the side affected. It is not an intercostal neuralgia, as in the pleurisy of the adult, a pain radiating in some of the nerve filaments of the abdominal wall. In the child attacked with pleurisy there is but slight fever; he sleeps badly, the appetite is diminished, and he complains of a pain in the abdomen, a pain which should immediately direct the attention of the medical man to the probability of the existence of pleurisy. The respiration is but very slightly accelerated, and the cough a little dry, does not present any particular features. Twelve or twenty-four hours afterwards percussion will reveal the existence of dulness, and a certain *bruit de frottement* will be heard by auscultation. The apnoea will be observed to be more or less complete; and when the child cries a veritable broncho-egophony will be perceived. The general condition of the child is so little changed that in most cases he can get up and go about as usual. As to the treatment of this last affection, M. Simon recommends dry cupping at the beginning and poultices. The next day or the following small blisters, left on for three or four hours and, when taken off, another poultice applied and left on for an hour, when the blisters will have arisen, and can be dressed. This revulsive treatment should be continued throughout the whole duration of the disease. As mixture he prescribes the following:—Tinct. scillæ, tinct. digitalis—of each 19 drops; syrup, one ounce; gum water, three ounces. A teaspoonful every two hours. The digitalis and the squills should be suppressed after four or five days. Milk should be freely given, as it acts as a good diuretic.

ACTIONS AGAINST MEDICAL MEN.—Two cases in which medical men played the principal rôle came before the French tribunals last week, and are not without interest, and perhaps something useful may be learned from them. The first was that of a man who broke his leg, and the fracture was complicated with a wound. The doctor of the village was sent for, and treated the case to the end. When he sent his note (£12) for attendance the patient refused to pay, and, being advised by another medical man, set up a

claim for £400 damages against his attendant, basing his claim on "forgetfulness or ignorance of all the rules of art, and in particular on the employment of perchloride of iron to arrest the hæmorrhage." A committee of experts designated by the tribunal composed of medical men drew up a report on the case, and having concluded in favour of their *confrère*, the man offered to pay the bill and withdraw the action; but to this the doctor refused, and brought his client into court for libel, claiming £200 damages. The patient was condemned to pay the original bill and £20 damages, besides having to pay all the expenses of the affair from the beginning to the end. It was a pity that the doctor who made the dastardly attack on his *confrère* under cover was not condemned to pay for his advice. The other case was very peculiar, both the plaintiff and defendant being medical men and both practising in a town famous for its mineral waters. An illiterate patient was sent to this place with a card from a doctor in a neighbouring town recommending him to the care of Dr. A. An omnibus conductor brought him to the house of Dr. B., who kept the card and the patient. A., learning the incident, was naturally little satisfied with the conduct of his *confrère* B., and meeting him in the street, publicly called him very offensive names. B., seeing that his position was compromised, summoned his enemy before the tribunal; but here the tables entirely turned, for B. was condemned to pay £200 damages to A., besides the expenses of the action. Dissatisfied at the issue of his process, B. appealed, but the Court of Appeal pronounced in favour of the judgment given by the inferior court, and thus ended the affair, and, I expect, the practice of Dr. B. in the picturesque town of St. Honoré les Bains.

Special.

OUR TROOPS IN EGYPT.

TELEGRAPHIC and other reports from Egypt during the past week have afforded us a good deal of information as to the conditions, sanitary and otherwise, of our troops engaged against the enemy in that country. It is perhaps in the nature of things that those reports should not be altogether in accord with each other, but such as they are, they enable us to gather the particulars which for the information of our readers we have collected, as follows:—

That in the first rapid advance from Ismailia the troops got ahead of their commissariat and transport was but a matter of course, considering the nature of the service in which they were engaged. For the first twenty-four hours they appear to have been without supplies; the native labourers fled, taking with them their animals. Soon, however, Bedouins brought in two hundred sheep, which they disposed of to the ruthless invaders of their desert home for twelve shillings per head. The neighbouring fields of maize supplied food for the jaded horses, and so all was well. More recently it is stated that there is difficulty in providing the men with tinned meats and with vegetables of good quality; also that the water of the fresh canal is fouled by dead bodies of men and animals. At Ismailia there are vessels on which water is being rapidly condensed. The fresh water canal has moreover been cleaned out, and its banks repaired where they had been injured.

The Sanitary Commission at Suez has already distinguished itself. Some cases—according to one account only two—of cholera having appeared on board ship with troops in the Red Sea, that learned and apparently numerous body held a meeting, with the result that the "doctors" differed among themselves—not by any means an unusual thing—as to the nature

of the measures to be taken. The upshot was that ten voted in favour of all ships from Bombay and Aden being subject to quarantine, and six against that measure. In the minority were one foreign and five English members.

Among the items taken into account as conducing to defence on the side of Arabi, and to the difficulties to be encountered by our forces, climate is enumerated. The fact is recognised that the temperature does not begin to moderate until about the middle of October, and that among the reasons for desiring a speedy end to military operations is the danger of sickness breaking out extensively in the forces engaged. This danger would be enhanced were Arabi to open the sluices of the Nile, but it is pointed out that the results of such a proceeding would cause greater inconvenience to him than to our troops. Not only have our troops to march over heavy desert ground, and to fight under the unfavourable conditions thus indicated, but in the absence of labourers they have also to do all the work of haulage and "navvies." In this they are by this time relieved by men imported from Cyprus.

At the affair of Kassassin, according to estimates formed, the strength of the British force engaged was 2,000; that of the Egyptians 13,000. In one place the men of the latter are described as the "flower of Arabi's army," in another as untrained Felaheen. According to one report the loss on the British side on that occasion was one officer and five men killed, five officers and fifty-six men—according to another, twenty-seven men, wounded. At all events, the circumstance is noteworthy that the officer who was killed was not a *combatant*, but a medical officer. As to the destruction to the enemy, it amounted, according to one account, to "thousands;" according to another, sixty-nine dead bodies were found upon the field of battle.

The accounts of the state of health of the troops vary. At Alexandria it was described as fair; yet endemic fever was on the increase, and one officer had died of dysentery. At Port Said dysentery from bad water is looked upon as more to be dreaded than battles against the Egyptians. At the front cases of sunstroke are said to be numerous, and it is remarked that the attack occurs for the most part in the morning.

At Ismailia the field hospital is established in the palace of the Khedive. After the engagement of Kassassin the patients under treatment included 93 wounded officers and men, 85 cases of sunstroke, besides others from bad water, doubtless dysentery and diarrhoea. Such of the patients as were in a fit state for removal were being "evacuated" to the hospitals afloat. The most recent accounts say that the sick and wounded together amounted to three hundred.

As an agreeable recreation in what would otherwise no doubt be intervals of idleness some "non-combatants" of sporting proclivities appear to indulge in their favourite pastime, their game Bedouins of the desert, their weapons, however, no more deadly than the field telescope with which the men in question are armed. But Bedouins when "stalked" are apt to become dangerous, and when brought to bay have on occasions been known to be somewhat dangerous "quarry." These wild Ishmaelites hover everywhere about the camps and battle-fields; they rob the living and pillage the dead when opportunity offers; perhaps, therefore, it is satisfactory to know that to them, and not to the Egyptian soldiers, are due the indignities to which the dead of both sides are said to have been subjected.

It is asserted (*New York Medical Journal*) that no authenticated case of rabies has ever occurred on the Pacific coast of America.

THE SICKNESS AND MORTALITY AMONG BRITISH TROOPS IN INDIA, AFGHANISTAN, AND BURMAH.

FROM the official reports to hand we have gleaned the following particulars in regard to the rate of sickness and mortality among British troops serving in India in the year 1880, that being the latest period to which published statistics have been brought down. The average strength in the Bengal Presidency was 31,585. Among these the ratios per 1,000 were, admitted 1,813; daily sick 75; death rate 27·73. Compared with 1879, when the death-rate was 29·87, that of 1880 shows a decrease equal to 2·14; but, whereas, in the latter year the death-rate by cholera was only 4·84, it was 8·95 in 1879, hence in 1880, as compared to the year preceding, there was an increase in the mortality rate in Bengal from other causes than cholera. In the Madras Presidency an average strength of 10,319 gave an admission rate equal to 1,868; daily sick 64; deaths 10·18. This extremely low death-rate is exceptional, if indeed, not unprecedented, among our troops in India. The invaliding rate was also only 20 per 1,000; cholera was almost entirely absent, only one death by that disease being recorded, and as indicated by the statistics, the general type of disease was unusually mild. In the Bombay Presidency the strength was 9,903. The ratios of admissions 2,150; daily sick 78; deaths 30·70; invaliding 49; equal to a yearly loss by these combined causes of 79·70, a ratio which must be looked upon as excessive, the more so when all the so-called sanitary and medical improvements of recent years are taken into account. As if to render this death-rate the more remarkable, the white troops in this Presidency were altogether exempt from cholera in 1880. It is observed that the chief factors of this death-rate were dysentery, diarrhoea, fever with bowel complication, or "enteric" fever, as that form of disease is often designated, remittent fever, and heat apoplexy or sunstroke. In Afghanistan the average strength of the Bengal white troops was 7,921. Among them the rates of admission were 1,527; daily sick 65; deaths 51. The rates of admission, and of daily sick are thus shown to have been higher than they were in 1879, but that of deaths is 37·12 less; the decrease being accounted for by the diminished frequency of cholera. Thus, whereas in the earlier year the rate of death among those troops by cholera was 38·42 per 1,000, they were in the later only 1·77; the contrast between those figures indicating the terrible extent to which during the first portion of the campaign, our soldiers suffered. Among the troops occupying the Khyber line from Ali Musjid to Gundamuck the death-rate in 1879 amounted to the enormous figure of 138·13 per 1,000, to which cholera contributed 74·03; and deaths by violence, in other words, casualties in battle, 46·93. In 1880 the rate of mortality in the same force was 71·40, of which a ratio of only 4·78 per 1,000 strength was by cholera, and 6·15 by casualties by violence, so that if these figures be deducted, the death-rate stands at 60·50, or 13·57 per 1,000 higher than in 1879. Among the fatal diseases, were diseases of the respiratory system, dysentery, and fever with bowel complication. In the Kurram Valley the rates of admission were 2,467; daily sick 91; deaths 45·07; of the latter, 3·75 were by violence, but cholera appears to have been entirely absent. The troops in Southern Afghanistan enjoyed better health than either of these columns. The total death-rate for the period of occupation was 49·00 per 1,000; but of this proportion 22·07 were due to casualties in battle, and other kinds of violence, leaving the actual mortality by disease equal to 26·93; cholera was absent during this time. In Burma the deaths among British troops amounted only to

18 in an average strength of 2,734, equal to 6·22 per 1,000. These figures indicate what must be considered to be an even more exceptional state of things than that which has been noticed in regard to Madras. It is right to observe, however, that in 1879 the ratio of deaths per 1,000 troops in Burma was 23·42.

THE EXODUS OF IRISH STUDENTS TO SCOTLAND.

EFFECT OF THE CHEAP AND EASY DIPLOMA COMPETITION.

THE following excerpts from the evidence submitted to the Royal Commission on the Medical Acts throws further light on the Scotch diploma traffic referred to in our issue of last week:—

[DR. ARCHIBALD H. JACOB, of Dublin, examined.]

I WOULD like to ask you whether in your opinion there is not a want of equality in the examinations, the curriculum, and the fees of these various corporations?—There is an excessive want of equality as regards Ireland, which I will illustrate by one or two figures. A person desiring to obtain the M.B. and M.Ch. degrees of the University of Dublin will have to attend thirteen courses of lectures, occupying at least three years in medical study. It will cost him £136 for his medical and surgical qualifications, besides £83 for the arts qualification, which is necessary to his obtaining these as a University student, making a gross total of £219 that that man will have to pay. The lectures are £61, the hospital £44, and the degree fees £31; that makes £136. If the same student desires to obtain the same degrees in the Queen's University he can obtain them upon lectures which may be put in in two years at an expense of £61. This is considerably less than half the expense of even the medical portion of his education in Dublin University, and it is one year less in the way of curriculum. If he desires he can obtain qualifications at the Apothecaries' Hall, with twelve courses of lectures, for £73; but if he wishes to obtain the Dublin double diploma, that is the licence of the College of Surgeons and the College of Physicians, it will cost him in three years £157. So that the expense of obtaining degrees varies in Ireland from £61 to £157; and the length of the curriculum varies from two years to four years.

May I take it that this is your meaning, that the result of inequality in the curriculum and the amount of fees is to drive students away from Ireland to other places at which the curriculum is shorter, and where the fees are lower?—Yes. To drive the students from those bodies which maintain a high curriculum, a high course of study.

A high course of study and a short curriculum, you mean, has that effect?—No, a long curriculum and a high course of study will drive them to other bodies which require a shorter curriculum and a lower course of study, whether those bodies be in Ireland or in Scotland. I took the Medical Students' Register, which is published annually by the Medical Council, for ten years, and I picked out from it all the Irish students, numbering 2,584; I followed those students into the Medical Register of Practitioners for the purpose of ascertaining where they obtained their licences. It will appear that out of 232 surgical diplomas granted by the Edinburgh College to Irish students, 54 were granted to students of the Queen's College, Belfast, 66 to those of the Queen's College, Cork, and 81 to those of the Queen's College, Galway; that is to say, that 151 out of the 232 came from the Queen's Colleges. Now, if you will permit me, I will explain the reason of that. A student attending in a Queen's College may obtain all the lectures necessary for a Queen's University degree, or a Scotch double diploma, in two years, not more than two courses of lectures being required in any subject. That student, if he were to come to Dublin, would be obliged to put in a third year, to attend a third course of lectures, pay for his maintenance in Dublin, and pay his fees. Consequently, he does not come to Dublin; but when he seeks a diploma outside his own University, he goes direct to the Faculty at Glasgow, or to the Colleges of Physicians and Surgeons at Edinburgh for it. Thus it turns out that a very large proportion of the Irish students have within the last fifteen or twenty years taken their qualifications in Glasgow or in

Edinburgh, in consequence of the fact that the curricula there are equal to the curricula of the Queen's Colleges, and below the curricula of the Dublin Colleges. Therefore I use these figures to enunciate the fact that that inequality has been productive of an enormous exodus of Irish students to Scotland; and that if that exodus, or that competition of curricula, is ever to be put a stop to, it can only be put a stop to by, to a certain extent, equalising the curricula, the fees, and the examinations.

Then will you tell me by what means you would propose to stop that inequality?—By the conjoint examination, as proposed by the Bill already before Parliament.

With regard to the number of students who leave Ireland in order to get degrees or diplomas or licences elsewhere, I think you said you had gone over a list of over 2,000?—2,584.

A considerable number, especially of the young men educated at the Queen's University, went to Scotland in order to get their licences?—Yes.

It occurs to one that it may be on account of the lower standard, either of examination or curriculum, or that the fee is lower; is the inducement, in your opinion, in this direction?—I am not in a position to form any judgment as to what the standard of examination is, but I am as regards curriculum and fee; and I believe the cause of the exodus of students is in consequence of the lower curriculum and the cheaper total cost of qualifications obtained in Scotland.

You are led to believe that it is in consequence of shorter curriculum and lighter fee that they go to Scotland?—Quite so.

It would be of great importance to ascertain whether anything of the same kind occurs with regard to any of our Irish institutions; do you know, as a matter of fact, whether any young men come to Ireland from either England or Scotland to pass at any of our licensing bodies?—I am only able to answer, with any degree of certainty, for the College of Surgeons, and I do not know of any young men coming from England or Scotland to pass at the College of Surgeons, except such as have come from England or Scotland and taken their education in Dublin; I do not know of any who have been educated in England or Scotland who have come to Ireland to take their qualification.

Then, in fact, you look for a remedy for this exodus of Irish students to an equalisation of the curriculum?—Yes, I do.

In talking of the reasons for which students go from Ireland to Scotland, you speak of Scotland as having the easier curriculum; that is to say, you believe it to have fewer rigid lecture requirements?—Yes.

And smaller fee?—Yes.

Should you attach very great importance to those matters as inducements?—Yes, certainly.

Should you regard them as vicious or objectionable inducements?—Yes; I certainly should regard the restricted course and the smaller fee as vicious inducements. I should not in the least object to a reduction of the curriculum if it was a universal reduction. My objection is not to the reduction of the curriculum itself, but to the fact that the reduction operates improperly by inducing men to go where they will get a shorter and easier course of study. I mean, shorter, in the sense of being less in extent.

You would, of course, consider it fatal to the public interest, if there were such differences of examination between Dublin and Scotland, that men should be able to go from Dublin and pass an examination in Scotland which might be below the proper requirements of the public?—Certainly I should.

(To be continued.)

THE Editor of the *Irish Medical Directory* will feel greatly obliged if those gentlemen who have not yet returned their corrected statement of qualifications, &c., for insertion in the *Directory* for 1883 will do so at once. He also solicits information as to inaccuracies, either of omission or commission, in last year's issue, as, in consequence of the difficulty of eliciting replies, he finds it almost impossible to eliminate all errors.

WEDNESDAY, SEPTEMBER 6, 1882.

THE SYMPATHETIC SYSTEM AND DISEASE.

THE vast majority of medical practitioners probably fail to attach all the importance they ought to the influence exercised over the progress of disease by the sympathetic nervous system, and it would be difficult, in the present state of our knowledge concerning the functions of this set of nerves, to fix any great amount of blame on those who do not fully appreciate the necessity of fully weighing the effects attributable to them. For a long time they have been a favourite subject of controversy with physiologists and pathologists; and as in the past most varying views as to their importance have now been urged and now denied, so in the present there exist two opposite schools of belief respecting their functions. In all scientific questions which occupy a debateable position, and which affect the profession, it is eminently desirable that periodical surveys of them should be made by competent inquirers for the benefit of the general practitioner, who cannot, by reason of his occupations, determine for himself amid the theories and statements made on different sides. Hence, as we have often observed, the advantages conferred by the delivery of such lectures as have been wisely provided for by liberal benefactors—lectures of which the Bradshaw Address, recently read before the Royal College of Physicians of London, by Dr. E. Long Fox, is an example—extend far beyond the immediate circle of those who actually hear them.

Their value is of necessity intimately dependent on the competency exhibited by the orators selected to deliver them; but so extensive is the field of choice open to the electors, that it may safely be said the lectures delivered at various times in the halls of the Royal College of Physicians are without rivals in any part of the world, both for the inherent excellence they exhibit, and for the influence they exert over the progress of scientific medicine. In this respect, the latest addition to their number, Dr. Fox's Bradshaw lecture on the "Influence of the Sympathetic on Disease," is a contribution deserving even extravagant praise. Although it is in great part a recapitulation of work already accomplished, yet it is so carefully constructed, and arranged with so much judgment, the facts that support theories, and the theories to which they lend importance, are so judiciously advanced and commented on, that none can fail to derive the utmost instruction from the demonstration Dr. Fox has provided.

Every physician has, some time or other, placed before himself the problem whether the sympathetic is, or is not, an independent system. Puzzled by the progress of a fever case, by the developments of hysteria or of hypochondriasis, or at a loss to account for apparently inexplicable disturbances of gastric or intestinal origin, he refers them, with a sort of hopeless energy, to the "sympathetic;" and it is no reproach to him that in barely one instance out of a thousand is the diagnosis advanced by intelligent understanding of what is involved in it. As Dr. Fox has observed, "the lesions to which the sympathetic is subject are manifold. In a large number of these coarser lesions the influence is not that of the sympathetic on disease, but of disease on the sympathetic;" and though this has apparently the effect of simplifying the matter to the comprehension, it really does not remove any of the complications surrounding it. So far as pathological data lend assistance, however, it must be said that a good deal is known now that was formerly hidden, and from the fact of certain lesions of parts of the sympathetic attending the presence of clinical symptoms, the presumption of a distinct relation between them is set up. Thus, quoting from Dr. Fox's address, "Both in ataxy and in tetanus redness of the semi-lunar ganglia has been observed. Inflammation of the semi-lunar ganglia has been associated with headache, hypochondriasis, vomiting, and death from marasmus; inflammation of the left portion of the solar plexus with pertussis, spasmodic vomiting and convulsions; inflammation of the ninth and tenth thoracic ganglia after retrocession of an exanthematous disease, with opisthotonos; vascularity of the sympathetic nerves in the chest, and of the semi-lunar ganglia, with tetanus; great increase in the size of the lower cervical ganglia, with cretinism, great increase in the size of all the ganglia with idiocy; enlargement of all the abdominal sympathetics and of the splanchnic nerves, with diabetes; increase in size of the semi-lunar ganglia with a case of tuberculous supra-renal capsule; increase of size of the same ganglia with cancer of the stomach." These changes are capable of being referred to the influence of disease on the sympathetic nervous centres, and in the light of

what is common knowledge regarding inflammatory processes it is not difficult to trace such effects to the influence of altered nutrition; while the consequences that follow from the disorganisation of important parts of an organic system like the sympathetic must necessarily be radiated in every direction from the injured centres. Whether we need to accept the theory of an independent activity for the sympathetic may continue to be doubted, but it is scarcely possible to explain all the observed effects attributable to it alone on other grounds. The occasional occurrence of anencephalous monsters, in which the sympathetic is the only nervous system present, is a strong argument in proof of such intrinsic independence; and the lessons of animal morphology afford even stronger indications of the correctness of this view. In a highly complex organism, however, when we find, as additional developments, and possessing superior endowments, a cerebro-spinal nervous system wholly supplementary to the sympathetic, it is not unreasonable to suppose that the latter will, under ordinary circumstances, be dominated by the former; and we may, perhaps, regard such a relation as that persisting under normal conditions of health. Whether, with altered circumstances, a higher degree of spontaneity is exhibited by the sympathetic, will in all probability continue to be a moot point as long as we are at fault in deciphering the nature of those changes which, because we cannot perceive them by any means as yet discovered, we agree to call molecular. Certain it is that secondary derangements do follow on the reception of primary lesions by the sympathetic centres, and that they are of sympathetic origin there is no room to doubt. Dr. Fox cites among such indications, flushing, sweating, tinnitus, headache, faintness, palpitation, constipation, diarrhoea, vascular intestinal congestion, diuresis, &c.

If once the independent action of the sympathetic is conceded so far as to admit that it is "one of the chief factors in inflammatory disease of every organ of the body," and that this is consequent on the influence it holds over nutrition and circulation, it will be difficult to escape the conclusion to which Dr. Fox evidently tends, and which would attribute no unimportant place to the sympathetic in every diseased condition of the body. This logically follows if it be assumed to have a part in the due performance of all the regular functions; but, as we have already hinted, this is by no means a commonly accepted axiom with the profession. That the significance of the sympathetic in health and disease deserves to be more fully considered and more generally regarded, Dr. Fox's lecture may have the effect of convincing the medical world. It can do no harm if his emphatic language excite inquiry and investigation; nay, vast benefits must follow should he be the means of creating distrust of the rough and ready practice that associates the sympathetic with the unknown; and, even though we may not be disposed to accept the full meaning of his utterances, the following portion of his closing remarks cannot be too attentively weighed and tested at every possible opportunity:—

"The influence of the sympathetic touches every normal function of the body, every abnormal disorder.

It is the connecting link for function between all organs ; its close brotherhood, I had almost said cohesion, with the cerebro-spinal nerves and centres brings into association in a thousand ways the purely nervous phenomena with those more primarily sympathetic ; it is frequently the seat of coarse lesions, but where the same symptoms are met with, when these coarse lesions or injuries cannot be recognised, it is only fair to believe in an irritability, a morbid condition of the sympathetic ganglia, the anatomical elements of which may probably present themselves to means of research, as these become more accurate.

"In congestion, in hyperidrosis, in some forms of angina pectoris, in sunstroke, in the regulation of vascular tone, and in its many abnormalities, in vaso-motor neuroses of the extremities, in symmetrical vaso-motor gangrene, in some varieties of aneurism and of albuminuria, in diabetes mellitus, in diabetes insipidus, in hysteria, hypochondriasis, and other forms of neurasthenia, in those Protean disturbances of the economy that are excited by emotion, and lastly in pigmentation, including Addison's disease, the influence of the sympathetic seems primary, and almost, if not wholly, independent. In inflammation, including practically inflammatory disorders of all organs, in fever, in hemiparesis, in exophthalmos, in progressive facial hemiatrophy, and in epilepsy, the part played by this system of nerves is secondary, though important. In most of these, however, as of other ailments, the cardiac phenomena, the conditions of vascular tone, the perspiration and diarrhoea, the marvellous influence of the abdominal nerves and vessels on the distribution of blood in the body, are evidences of collateral and coincident disturbances of the sympathetic.

"This system is far more than a chain of transmission from the higher nervous centres. It often stands alone ; far more often in correlation with the cerebro-spinal system."

THE DUTIES OF A BRANCH MEDICAL COUNCIL.

APPROPOS of the evidence given by Dr. William Stoker, of Dublin, before the Medical Acts Commission, on which we commented in our last issue, we would like to ask a question to which we solicit a reply from any of the representatives on the General Medical Council, either of the University of Dublin, the Queen's University, the College of Surgeons, the College of Physicians, or the Irish Apothecaries' Hall, who constitute the Branch Medical Council for Ireland.

We want to know why it is that not one of these gentlemen, nor any one of the deceased Crown representatives for Ireland ever breathed a word to the Medical Council in reference to the traffic in sham certificates in Dublin ; the tricks perpetrated in Dublin with reference to medical teaching ; or the trade in diplomas worked—as Dr. William Stoker points out—between the Irish Apothecaries Hall and the Scotch Colleges ?

In Dr. Jacob's evidence before the Royal Commission we find the following :—

You state that the Council "has 'recommended' changes for the better, but, lacking the courage to battle with the vested money interests of individual institutions, has permitted its 'recommendations' to be habitually set at nought." Do you still hold to that view ?—I do. As a matter of fact, its recommendations have been habitually set at nought. For instance, it is one of the recommendations of the General Medical Council that not less than four years should be occupied in medical study. It is notorious that two years and nine months has been

occupied in medical study ; and as two years and nine months has been a frequent period for obtaining a medical licence, the recommendation has been disregarded in that respect. I have reason to know that that has been set at nought. Again, it has been one of their recommendations that no man should obtain his qualification before he was twenty-one years of age, and that preliminary examination should always precede medical study. I am aware, as a matter of notoriety, that these recommendations have been in certain cases set at nought.

You have referred to three matters as to which I confess it seems to me that you believe the Medical Council to have virtually connived at an evasion of its regulations in three important particulars ?—I did not desire to imply that the Council as a whole connived at it. I stated that those recommendations were, as a matter of fact, evaded, and that the Medical Council did not enforce them ; but I did not suggest that the Medical Council as a whole was cognisant of it, and notwithstanding such cognisance, permitted the thing to continue.

I think I understood you to say, emphatically, that it was notorious ?—So it is notorious.

And, being notorious, you would expect that the twenty-four members of the medical profession (it being part of their business) should know it ?—I think it would be strange if they did not know it.

There can be no doubt that the word "notorious" used by Dr. Jacob was fully justified. Every medical teacher in Dublin has for years known of the prevalence of the sham certificate system ; the trade in half-diplomas between Dublin and Edinburgh ; the admission of boys to the profession ; the evasion of one of the four years of medical study ; and the admission of students to the study of the profession before either preliminary examination or registration. And yet—except when Dr. Haughton once let drop a chance word about sham certificates which he afterwards flinched from justifying—no whisper of these abuses seems to have ever reached the General Medical Council from any member of the Branch Council.

Nay, more—it is on record on the face of the minutes of the General Medical Council, that when that Branch was forced by an order of the Council to make an appearance of investigating the sham-certificate abuse, and when the true facts came before them, admitted by those responsible, they refrained either from taking any steps or expressing any opinion thereon.

On this subject Dr. John William Moore, representing the Irish Medical Association, gave the following testimony :—

Supposing that the general principle which you were suggesting were acted on, that the licensing bodies should insist strictly and literally upon the corporeal attendance of students at all those lectures, do you think it would be very easy to enforce that rule ?—Your question raises one or two very important points. First of all comes the general question, whether lectures are of any use at all or not ; but what we do feel is this, that so long as the licensing bodies have courses of lectures the attendance on those courses of lectures should be *bona fide*, otherwise the moral effect on the lecturer and on his class is most unfortunate. It is a falsehood, the whole thing from beginning to end. The lecturer enters the names of a number of gentlemen, and gives them their certificates, and those certificates are worded "Mr. So-and-so has attended, or has diligently attended, those lectures." I am a lecturer myself, and I positively refused to sign my name to any such document as that, and my colleagues did the same, so that the result of the action of myself and my colleagues has been to insist upon an absolute *bona fide* attendance at our lectures in the Carmichael

College of Medicine. The required attendance amounts only to half the course, but it is better to have that than none at all, if the lectures are to remain obligatory.

Of what value, we ask, is a Branch Medical Council which deliberately conceals the existence of the grossest abuses from in the General Council? Is it not high time to wipe out the system which tolerates such a condition of things and to substitute for such "representatives" as these some gentlemen who have no interest in concealment, but have the courage to do their duty with respect to abuses.

Notes on Current Topics.

The Fortune of War.

THE medical profession sustained a not inconsiderable loss in connection with the engagement between our troops and the Egyptian rebels at Kassassin, the only fatal injury among officers on that occasion being sustained by Surgeon-Major Shaw of the Army Medical Department. This fact is a somewhat grim commentary on the action which denies to medical officers on service during war any rights except those accorded to non-combatants, and with such information as we have already received concerning the conduct of those who are now in Egypt as medical attendants on the army it is easy to perceive the injustice of withholding the rank proper to men who risk at least as much as any of the actual fighting class. No better proof, for all it is a mournful one, could have been given by the deceased surgeon to show how zealously he performed his duty, and we cannot but regret that his life should have fallen forfeit to his exertions. The late Surgeon-Major was a graduate in medicine of Queen's University, Ireland, and became assistant-surgeon in the army in 1863, surgeon in 1873, surgeon-major in 1876.

As an example of the steady coolness and intrepid bravery exhibited by the medical staff on the field of battle, the *Standard* recounts the following incident of the first bearer company of the Army Hospital Corps at the Kassassin engagement:—Through some movement of the troops the bearer company was isolated, and it became clear that if their safety alone were consulted a change of position would have to be made. As this, however, would have led to interruption in the dressing of the wounded, on which the medical officer in charge was busily engaged, he refused to permit any movement, and his spirit becoming infused into the men, they heartily seconded his determination. In order to make a shelter they filled their haversacks with sand, and then, using the rifles of the wounded, vigorously repelled the enemy's attack, to which they were exposed, until the arrival of the cavalry secured their safety. The name of the medical officer who thus vindicated the reputation of his order is not given in the descriptions hitherto received, but doubtless it will not long remain undiscovered. Whoever it was, he nobly discharged his duty.

It is not improbable that a further staff of female nurses, chosen from amongst those trained at Woolwich and the Royal Victoria Hospital, Netley, will be shortly despatched to the seat of war.

Infectious Hospitals for Kent.

THE importance of providing hospital accommodation for the reception of cases of infectious diseases is becoming much more generally recognised and acted upon now than formerly, and in certain districts considerable energy is displayed in making the needed arrangements to this end. Kent has hitherto been altogether without such institutions, but the first erected for the purpose has just been completed, and is ready for occupation. It is situate at Sittingbourne, and has been erected, at a cost of £5,000, by the united sanitary authorities of the Milton Union. Other hospitals of a similar description have either been commenced, or are in contemplation, at Maidstone, Chatham, and Faversham, and there can be no doubt felt respecting the advantages that will be likely to result from their existence when occasion arises for them.

Prize-fighting.

MUCH as we may be inclined to regret any indications of a falling off in the national devotion to manly athletics, there can be no possible excuse for retaining an institution of so barbarous a nature as prize-fighting. In whatever sense it is regarded, this brutal pastime is eminently degrading; it entails an amount of punishment on the principal actors which is within very "measurable distance" of fatal injury; it is even more destructive of better feeling and humanity than it is of facial beauty; and, prosecuted as it must be, in this country, it is necessarily demoralising to every one who participates as a spectator in the excitement of the battle, inasmuch as they can only do so with the consciousness of breaking both moral and legal statutes. The effects that will surely follow on widespread repetition of the scenes formerly too common in connection with prize-fighting are too serious to be patiently anticipated, and we may be permitted to hope that the disgraceful combats recently entered on may be among the last to be reported. Magistrates undoubtedly, by their lenient sentences, indirectly encourage the spirit which gives rise to such contests. It is surely no punishment to a person of degraded and brutal instincts to require him to find sureties for his good behaviour, or else go to prison for three months—this being the decision recently given by magistrates in a prize-fighting case. We are as much, and possibly very much more, interested than any other profession in the effacement of the spirit which incites to these encounters; and we are fully justified in demanding that, as a matter of public necessity, those who offend against the law, either by fighting or abetting those who fight, shall be brought to punishment of sufficient severity to deter them and others from further wrong-doing in the same direction.

NINETEEN persons were summoned before the Leiceaster magistrates on Friday for non-compliance with the Compulsory Vaccination Act. In almost every case conscientious objections were urged, while in several instances death and injury in the families concerned were alleged through the effects of vaccination. Fines of 10s., or, in default, seven days' imprisonment, were inflicted in eighteen cases, the other being adjourned.

The Spread of Disease.

It is interesting to note that, at the present time, when we have just received the report from the Commission on the Contagious Diseases Acts, the American medical profession is also turning its attention anew to the same subject. The *Boston Medical and Surgical Journal* observes that "it is somewhat singular in this country (*i.e.*, America) there should be carefully exempted from all regulation or repressive measures a single disease, or rather a set of diseases, and this not because of their insignificance, but simply because of their mode of communication. If a man have small-pox he is hurriedly isolated, and all possible danger to his neighbours carefully prevented. If he have a greater disease, he is at liberty to spread it, as his ignorance or wickedness may direct." The same paper goes on to admit that "the difficulties in the way of its regulation are numerous, lying partially in the nature of the subject, but in great measure in the delicate sensibilities of the religious world, which refuses to consider so unsavoury a subject." It then proceeds to note the provision of a proposed Act, to the effect that infected persons might be removed to special hospitals if deemed necessary for the welfare of the State. Such a measure is, however, deemed impracticable; but the *Journal* thinks, and rightly, that some good will flow from discussion of the question every time it is reopened.

The Association for Opposing Compulsory Notification of Infectious Diseases.

As the subject of notification by medical men had been discussed at Worcester by the British Medical Association, it was thought desirable to ascertain whether any change had come over the views of the members of the opposing Association in consequence of that discussion. A meeting was accordingly held in Liverpool last week, and a test resolution put to the vote, declaring that the views of the meeting were the same as those expressed at the meeting held in July last. This was carried by an overwhelming majority, there being but two against it, in a meeting composed of about sixty members. A committee was afterwards appointed for the purpose of conferring with the Liverpool Health Committee as to the best method to adopt to ensure the early notification of infectious disease without saddling the medical profession with this odious task. The conference has not yet taken place; but the Health Committee, the Chairman of which had intended making an effort to apply this year to Parliament for power to adopt the objectionable Act, have been requested to postpone taking any steps until an alternative can be proposed by the Association. The Chairman of the Health Committee, who imagines he has a keen insight into human nature and knows the mind of the profession better than it knows itself, thinks that medical men will be glad to tell all they know, provided only that they get official sanction for doing so, and that their present attitude is put on for appearance's sake only. Being thoroughly convinced of this, he would then, in the most friendly manner possible, force the Act on them, which by a little gentle coercion would be doing for them the very thing they would like to do, only it would not do to let this be known! Query regarding the conference

above mentioned: Is not the Association overstepping its bounds by proposing? It was formed for the purpose of opposing, not proposing.

A Struggle for a Fever Corpses.

A SAD scene, one illustrating the absolute indifference existing among the lowest classes to infection, or how it is spread, occurred at Birkenhead last week, at which place an elderly man named Busede was charged before the borough magistrate with obstructing the health officers in the execution of their duty. From the evidence adduced, it appears that the health officers, in the discharge of their duty, went to remove the body of John Briscoe, who died of typhus fever, from a house in Albion Street, where it had been lying several days, when they found about twenty people in a small room, with the body, eating and drinking. The defendant threw himself on the coffin, and said it should not be removed. His friends supported him, and a struggle ensued, during which the coffin lid was torn off. Ultimately the officers removed the body to the mortuary. The defendant was fined 20s. and costs. We question whether a cat-o'-nine tails would not have been the most fitting punishment for such diabolical conduct.

Notification of Infectious Disease.

THE following is the statement of opinion which was presented by Dr. Jacob at the meeting of the British Medical Association:—

We, the undersigned medical practitioners in Ireland, are of opinion—

1. That the proposal to compel medical men, without any discretion, to report cases of infectious disease either to the custodian of the patient or to the sanitary authorities is an unwise interference with the relations in which such medical men stand with their patients.
2. That the dread of the consequences of notification would be likely often to lead to concealment of disease by the public, and to the exclusion of the medical practitioner with that object, and that, thereby, disease would probably be extensively spread owing to the absence of the precautions which, under the advice of the physician, are now usually adopted.
3. That the imposition of the duty of reporting all infectious cases would be so irksome and prejudicial to the interests of practitioners, that it might probably be frequently evaded, and thus those practitioners who felt it their duty to comply conscientiously with such law might be placed at a disadvantage in the practice of their profession.
4. That any project of law which would place the physician in the position of appearing in the witness-box to testify against his patient ought to be energetically opposed.

We, therefore, are of opinion that in the interests both of the public and the physicians the proposal to compel practitioners to report directly or indirectly all cases of infectious disease to the sanitary authority ought to be resisted by the profession.

Signed by over six hundred Irish medical practitioners.

The Spread of Cholera.

CONSIDERABLE anxiety is felt, not only in foreign countries, but also at home, on account of the serious progress Asiatic cholera is making at various stations. At Manila three hundred deaths from this cause alone occur daily; an outbreak is also reported nearer home, at Tangiers, on the shores of the Mediterranean; and at Alexandria the utmost precaution is now being taken to prevent, if possible, its introduction among our soldiers and sailors in Egypt, cases having been brought to Aden and Camaran on board a vessel from Bombay. Of course quarantine is the measure upon which reliance is placed by the authorities, and this is being rigorously enforced, much to the annoyance and perturbation of ship-owners. Although we do not share in the present freely-expressed fears of its migration so far westward as this country, nor think there is any tangible excuse for panic, those who have the care of shipping should nevertheless assist, rather than growl at the authorities for taking these very necessary precautions, because if an authenticated case found its way to these shores, the present trifling inconveniences would be materially increased by quarantine at all our ports. The last serious visitations to this country were in 1848 and 1856, since which one or two isolated cases only have occurred. Petenkofer's is the latest scientific treatise published on cholera in this country, and on the strength of being forearmed, many will doubtless study this book at the present juncture.

The Status of Queen's University Graduates in the Royal Irish University.

THE following letter has been received by a graduate of the Queen's University in answer to a question and application in reference to the position of Queen's University graduates in the new Royal University of Ireland:—

“Royal University, August 10th, 1882.

“Sir,—We beg to acknowledge the receipt of your letter of the 9th instant. With reference to your question whether graduates of the late Queen's become graduates of this University, we can only quote the words of the Act of Parliament 42 and 43 Vict., c. 65, s. 11: ‘All persons who at the time of the dissolution of the Queen's University are graduates of the Queen's University shall forthwith become graduates of the University constituted under the provisions of the charter mentioned in this Act with corresponding degrees.’ That section has conferred upon all graduates of the late University, degrees in this University corresponding to those they held in the Queen's University. We believe that, according to the opinion of the English law officers, the proper mode in which the medical graduates of the Queen's University shall now appear upon the *Medical Register* would be somewhat as follows: 1875. Jan. 19th. —. Name, —. Address, —. M.D. 1873, Royal University of Ireland; with a note indicating either to each name, or generally to all, marked, say, with an asterisk, that degrees of the Royal University dated prior to February 3rd, 1882, were obtained in the late Queen's University in Ireland. We do not think our Senate would confer the degree M.D. upon a person who has the degree of an earlier date; but,

if you desire to make any formal application on the subject, we will bring before the next meeting any letter you may address to the Senate on the subject.—Yours faithfully, J. C. MEREDITH, D. B. DUNNE, Secretaries.”

Medical Heroism.

WE publish in another column an interesting lecture by Dr. Tholozan, on the Plague. In spite of all the fogs of our own country, the thousand and one grievances of which we complain, Great Britain is a more desirable residence for practitioners than the land rendered familiar to readers of poetry by the beautiful poem of Moore—the “Veiled Prophet of Khorassan.”

“In that delightful province of the Sun
The first of Persian lands he shines upon,
Where all the loveliest children of his beam,
Flow'rets and Fruits blush over every stream.”

There lurks a deadly enemy to man in the shape of the plague. The fate of the physician and of his relatives is a sad family history. His death points out some lessons.—1st. He died at his post, like a hero. No doubt his life was one of labour and self-sacrifice, and some rude cross will alone mark his grave. Hippolyte Fauvel, the brother of Ch. Fauvel, a well-known French practitioner, has written a beautiful poem on the village practitioner. It is so appropriate that we transcribe it without translation:—

C'est le medecin du village,
Obscur, ignoré, méconnu,
Le dévouement est son partage,
Quelqu'un souffrait; il est venu.
Il est nuit, et sur la campagne,
La neige étend son blanc linceul,
Qu'importe! un pâtre l'accompagne,
Les enfants l'attendent au seuil.
Il entre dans l'humble chaumière,
Pas de pain, souvent pas de lit!
Sur un grabat se tord la mère...
Il paraît, console et guérit.

Frère salut à toi, dont la modeste vie
Est un long sacrifice! à toi que l'on oublie,
Et qui trouves toujours dans la fond de ton cœur
Un courage éprouvé pour cet ingrat labeur.
Frère! salut à toi! Tu fus la Providence,
Des pauvres ici-bas! La-haut ta récompense!

2nd. The physician carried the plague to Khelat-Arab from Bendagabad. The second lesson is a serious one. Medical men may become disseminators of disease, as in this case. The obvious conclusion is that, in the case of plague, the medical man should confine his attention to the infected centre, and not visit localities where the disease does not exist. Can this be done? The next point is, the medical man should use strict precautions and antiseptic measures on his own person, so that if he has to visit other families he may not infect them. Change of clothing, washing the hands, &c., are some of the most important precautions. We trust Dr. Tholozan will direct the attention of the authorities at Teheran to this danger, and that a sufficient supply of medical men will be procurable in case of other outbreaks of plague in Khorassan.

ACCORDING to M. Dareste (*Comptes Rendus*) monstrosities may be produced, in birds, by simply prolonging the interval between the laying of the eggs and the commencement of incubation.

Indiscreet Touting.

THAT zeal oftentimes outruns discretion was never more aptly illustrated than when, a few days ago, a house-to-house collection, in aid of the "West Kent General and County Ophthalmic Hospital," was determined upon by the management, Hastings being selected as a most likely field for the experiment. *En passant* we should like a little information as to the whereabouts of the hospital with so grandiloquent a title. And further, provided such a *bonâ fide* institution exists, and is in need of funds, we would ask why a town on the south coast of Sussex should be selected for the polite attention of canvassers for the support of a hospital in West Kent? Hastings is well known for her beneficence in the cause of charity; but Sussex, like every other county, has her own hospitals, none of which are too well off, whilst Kent is sufficiently rich, and has shown herself willing to have the care of her own *bonâ fide* charities. Probably the good people of Hastings also argued thus, as a correspondent informs us that many looked upon the house-to-house visitation in such a cause as a mild joke, whilst others were indignant at the attempt to divert their funds into less legitimate channels. In any case, the house-to-house touting of a large and rich town of 40,000 inhabitants resulted in the attainment of about £4, which, when placed in parallel columns with, perhaps, ten times the amount as expenses, will doubtless exercise a deterrent influence upon the minds of the promoters of the "West Kent General and County Ophthalmic Hospital" when seeking for fresh fields and pastures new.

The Newest Bacillus Discovery.

THE *Detroit Lancet* says that a Wisconsin doctor, in careful observation of his last thirty-six cases of fracture of the legs of railway employes, finds in the trousers of each case a parasite which he claims produces the broken legs. His proof is that he has placed some of the trousers containing the parasite upon the legs of some cats, and subsequently he found the cats in rat traps with their legs broken. The same inoculation of his wife's cows, which pasture in a field through which a railroad runs, resulted in finding many of them with legs broken. The doctor suggests that by cultivating this parasite in cattle and then inoculating men with it we shall be enabled to rid the world of the parasites which produce broken legs. Should it prove that the inoculation of trousers with such parasite will protect against broken legs the name of Buhl will rank with that of Jenner, Pasteur, and Koch.

THE annual death rate in the large towns from diseases of the zymotic class is still much under the average of past years for the season; last week it registered but 4·6 per 1,000; the rate in the several towns ranged upwards from 1·4 and 1·7 in Halifax and Bristol, to 10·2 in Wolverhampton, 10·5 in Nottingham and Hull. The highest annual rates from whooping cough were 2·7 in Oldham, and 2·8 in Plymouth; from scarlet fever, 1·4 in Salford and Oldham, and 1·5 in Blackburn; from measles, 5·6 in Huddersfield; and from fever, 1·0 in Blackburn, and 2·7 in Preston. The deaths from diphtheria included 18 in London, 9 in Glasgow, and 3 in Birmingham. Small-pox caused 2 deaths in Newcastle-upon-Tyne, and one in London.

The late Surgeon-Major Landon.

THE memorial brass to this young medical officer has recently been placed in the Hospital Church of St. Bartholomew-the-Less, and bears the following inscription:—

His Former Medical Contemporaries
at St. Bartholomew's Hospital have set up this Tablet
To keep in Memory the bright example of

ARTHUR JERMYN LANDON,
Surgeon Army Medical Department,
who, while continuing to dress the wounded
amid a shower of bullets in the action on Majuba Hill,
was in turn mortally wounded.

His immediate request to his assistants,
"I am dying; do what you can for the wounded,"
was characteristic of his unselfish disposition.
His habitual life was expressed in the simple grandeur of
his death.

He was born at Brentwood, Essex, 29th June, 1851;
died two days after the action,
at Mount Prospect, South Africa, 1st March, 1881.

The Civic Hospitality to the Medical Congress.

FROM the account of the receipts and expenditure of the Corporation of the City of London for the financial year just published, it appears that the expense of the *conversazione* to the International Medical Congress, last year, amounted to £2,099.

Memorial to Von Grafe.

A MEMORIAL statue of the eminent ophthalmologist, Albrecht von Grafe, was recently unveiled, in the University of Berlin, in the presence of a large assemblage, including several Government officials; the professorial staff of the University; von Grafe's son and daughters; his cousin, Professor Alfred von Grafe of Halle, and other members of his family; and also several ophthalmologists from distant parts, among whom was Professor Arit.

Does Compulsory Notification lower Death-rates?

DR. CARTER, of Liverpool, addresses to the *British Medical Journal* a letter on this subject, in which he observes that in the number of the *Journal* for January 7th, 1882, the "Edinburgh Correspondent" gave the following as the mortalities per 1,000 for that city during the six years 1876 to 1881 inclusive: 19·51, 20·86, 21·53, 19·06, 21·05, 20·06. These figures give an average annual mortality of 20·24 per 1,000 for the four years before the acquisition of compulsory notification, and 20·55 per 1,000 for the two years since. As this reported rise in the general mortality of the city did not seem to him to be the best proof of the "entire success" claimed by Dr. Littlejohn in the Public Medicine Section for the Edinburgh Act, Dr. Carter asked him, at the general meeting on the day following—the 11th instant—if the figures which showed such a result were correct. He categorically denied that they were so, and Dr. Carter now demands that the informant of the *British Medical Journal* will give his authority for the figures and justify his statement.

Query—Touts or Examiners?

THE *Philadelphia Reporter* says that, "in order to facilitate the admission of students and to aid the upward tendency of medical education," the authorities of the University of Pennsylvania have appointed physicians, graduates of that school, in the different prominent cities, remote from Philadelphia, whose duty it shall be to examine candidates for admission into the Medical Department. By this means the applicant is spared the expenditure of time and money necessary to a trip to this city on an uncertainty. Truly considerate towards the student!!!

THE Chair of Natural History in the Queen's College, Cork, is now vacant, in consequence of the death of Professor Leith Adams. The appointment is in the hands of His Excellency the Lord-Lieutenant, and the candidate selected will enter upon his duties about the middle of October.

THE absurdity of the English law against vivisection is well illustrated by a remark of Sir James Paget. He says, "I may pay a rat-catcher to destroy all the rats in my house with any poison he pleases, but I may not myself, unless with a licence from the Home Secretary, poison them with snake-poison."

AN alarming epidemic of dysentery is reported in some parts of Sweden. In Malmö last week there were about 1,000 sick, and the mortality was increasing. The schools are closed in consequence. Quarantine has been established in Copenhagen, and it is expected that it will be ordered in the German seaports of the Baltic.

AN epidemic of diarrhoea is raging with considerable virulence in New York and Brooklyn, where, according to the last official weekly returns, the death rate has risen to the enormous figure of 52 per 1,000 of their populations. During the same period the mortality in London was only 18 per 1,000, Paris 24, Berlin 33, and St. Petersburg, the most unhealthy city in the world, 45.

IT is rumoured that the Government are contemplating the abolition of the Queen's Colleges in Ireland, and that inquiries are being made as to whether the several professors will be willing to compound for a fixed sum, should the institutions to which they belong be closed. We do not believe the Government have ever dreamt of such a movement, and we really do not understand why the idea should enter the 'official' head, unless it seemed good to save the Parliamentary grant by sacrificing these institutions.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Derby 13; Bristol, Edinburgh 16; Halifax, London, 18; Birkenhead, Brighton, Glasgow 19; Cardiff, Norwich, Leicester, Portsmouth 21; Sheffield, Bradford 22; Dublin, Blackburn, Bolton 23; Huddersfield 25; Oldham, Plymouth, Sunderland, Preston 27; Liverpool, Nottingham, Newcastle-on-Tyne, Leeds 28; Manchester, Birmingham, 29; Wolverhampton 31; Salford, 32; Hull 34.

IN the Health Department of the approaching Social Science Congress three special questions have been put down for discussion—viz., 1. How does the employment of mothers in mills and manufactures influence infant mortality, and ought any, and if so what, restrictions to be placed on such employment? 2. What reforms are desirable in the administration of hospitals? 3. What are the advantages of a system of notification of infectious diseases, and what are the best means of carrying the same into execution?

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 21, Bombay 24, Madras 27; Paris 24; Geneva 18; Brussels 25; Amsterdam 23; Rotterdam 18, The Hague 23; Copenhagen 28; Stockholm 27; Christiania 26; St. Petersburg 45; Berlin 33; Hamburg 24; Dresden 27, Breslau 35, Munich 26, Vienna 22, Prague 25, Budapesth, 29, Trieste 32, Rome 24, Naples 34, Turin 23, Venice 23, New York 52, Brooklyn 52, Philadelphia 31, and Baltimore 26.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE EXTRA-MURAL SCHOOL, EDINBURGH.—Dr. Alexander Millar has been elected by the Surgeons' Hall division of the school to take the place of Dr. Heron Watson, who has discontinued lecturing on Surgery. Dr. Macgillivray is to lecture at Minto House in the place of Mr. Chiene. Dr. Angus Macdonald will not again lecture on Midwifery, so that the post of lecturer on that subject during the winter is at present vacant. This want is not so severely felt, as the subject is so ably handled by Dr. Croom in the summer, whose class during last summer numbered over 120 pupils, nearly all of whom were University students, anxious to learn their midwifery from so able a teacher.

A MEDICAL CONTEST FOR WORKMEN'S VOTES.—An appointment of considerable pecuniary value as surgeon to the Blochairn Ironworks is at present vacant, and there is quite a host of eligible candidates. The appointment is by vote of the men, and measures have been adopted to influence this vote, hitherto unknown in medical contests. Placards are displayed in the district, after the manner of municipal and political contests, soliciting votes for given individuals. On one is displayed—"Why vote for ———? Because he is a gentleman." It is not very complimentary to the medical profession that out of forty candidates for an appointment there should seem to be such an absence of this essential qualification. We hope this objectionable form of canvassing is not countenanced by many of the candidates.

STIRLING.—BOY POISONED THROUGH EATING WILD BERRIES.—A boy, about four years of age, died at noon on Saturday, the 26th ult., at Stirling, from poisoning through eating the berries of the "deadly nightshade." The deceased, along with a number of companions, had gone on the previous afternoon to a field to amuse themselves, and seeing the berries, he plucked some and ate them. After reaching home he became sick, and afterwards showed signs of delirium. He was taken to the Infirmary, but nothing could be done for him.

GLASGOW DEATH-RATE.—For the week ending with

Saturday, the 26th ult., the death-rate of Glasgow was 20 per 1,000 per annum of the population, as compared with 22 per 1,000 in the preceding week, and 20, 21, and 19 for the corresponding periods of 1881, 1880, and 1879.

EDINBURGH.—HEALTH OF THE CITY.—The mortality of Edinburgh fell from 72 to 65 during the week ending with Saturday, the 26th ult., being equivalent to an annual death-rate of 15 per 1,000. Under 1 year there were 26 deaths, and above 60 years, 7 deaths. The deaths from zymotic causes comprised 1 from scarlatina, 1 from whooping-cough, and 1 from erysipelas.

DR. LIDDELL, OF THE GOVAN BOARD, ACCUSED OF INHUMANITY.—Doubtless to some extent continual association with suffering and wretchedness begets callousness of heart, but to the credit of the profession, it can be said that such charge is not often justly attributable to medical men. We are sorry, therefore, to observe that such an accusation was preferred recently against the parochial surgeon of the Govan Poorhouse, under the following circumstances, which certainly do not seem to justify the amount of attention bestowed on so trifling an occurrence by the Glasgow newspapers. It appears that an accident occurred to a child outside the Poorhouse of which Dr. Liddell is medical officer, and that Dr. Liddell on being requested to attend the case refused, on the ground that "it was as much as his place was worth" to do so. At a meeting of the House Committee of the Poorhouse, at which Dr. Liddell was present, the matter was brought up before him. He had admitted that he refused to attend the accident, but said he had no idea it was such a severe case, otherwise he would have attended. Of course the House Committee could not control the doctor's movements outside the gates of the establishment, but they told him very distinctly as a mere matter of humanity he might have gone out. It seems clear that, in a crowded locality, consisting principally of tradesmen employed in ship-building yards, if the impression got abroad that the surgeon of the Poorhouse is bound to attend accidents outside the establishment, demands might be made on his time incompatible with the performance of his duties to the establishment, and it should be distinctly understood that, where there are so many surgeons in private practice, only very exceptional circumstances would justify Dr. Liddell's interference. In view of the case as stated by Dr. Liddell, he is to be entirely acquitted of the charge of "medical inhumanity at Govan," and we repeat that the newspapers have, as usual, made too much of a very paltry affair.

Literature.

CHRONIC BRONCHITIS. (a)

THIS little volume deals with a somewhat hackneyed subject and one on which it might be supposed little or nothing fresh could be said. It is, however, very pleasant reading, and the reader may pick up many a useful hint from a perusal of its pages. In successive chapters it deals with the objective and subjective phenomena, pathological relations, forms, and treatment of the disease in question. Dr. Fothergill says that his first experiences of practice (in Westmoreland) brought him much into contact with cases of chronic bronchitis which prevail largely in the damp and cold climate there, and he alludes, in passing, to a curious custom prevalent among the old people—especially the males of that shire—viz., that of betaking themselves to bed at

(a) "Chronic Bronchitis; its Forms and Treatment." By J. Milner Fothergill, M.D. Edin., M.B.C.P., Senior Assistant-Physician to the City of London Hospital for Diseases of the Chest. With numerous illustrations. London: Baillière, Tindall, & Cox, 1882.

the approach of winter and there remaining snugly ensconced until, with the coming of spring, a warmer temperature is ushered in.

In the first few chapters some paragraphs seem in rather doubtful taste. The following is hardly the sort of writing we should expect from a cultivated physician:—"Along the southern coast, as at Ventnor, or Hastings, or Torquay, sheltered from the east winds, may be seen in spring the choleric, high-complexioned old squire, who has left, sorely against his will, his old home and his ancestral acres during the March blasts, taking a constitutional in the sun, and finding fault with most things in this imperfect world, and severely taxing the patience of his spouse by his somewhat acid criticisms, and remarks as acid as his own phlegm." In the following chapter we meet with the remarks:—"Had Walsh's power of reasoning upon his observations been equal to his marvellous power of observation, he would have been one of the grandest teachers in the history of medicine. But to observe facts without carefully reasoning upon them, is a comparatively sterile form of talent: instead of the wide grasp of the trained thinker, it reduces the intellectual powers till the observer is little more than 'the sense-machine which registers observations.'"

Dr. Fothergill enumerates the following varieties of chronic bronchitis:—Dry, asthmatic, catarrhal, cirrhotic, emphysematous, degenerative, mitral, gouty. At page 95 the author somewhat egotistically quotes, from an article in the *American Journal of the Medical Sciences*, a passage in which Dr. Da Costa refers to his (Dr. Fothergill's) brilliant descriptions! The chapter on treatment is perhaps the best. It opens with the significant statement that the first thing is to teach the patient how to cough. To cough efficiently, the lungs must first be filled and vomiting may thus be avoided. The author speaks very strongly of the value of warmth, and very properly condemns the insane practice of coddling all day and then going direct to a cold bed in a cold bedroom. He gives a personal reminiscence to emphasize the point. He also alludes—and not unnecessarily—to the danger of cold water closets. In the section of stimulant expectorants we find, of course, the author's views on strychnia expounded. He says that at the Victoria Park Hospital he finds the following mixture very useful:—

R Ammon carb., gr. v.;
Tr. nucis vom., mx.;
Tr. scillæ, fl. 3ss.;
Inf. serpentariæ, ʒj. t. d. s.

The illustrations are very good, even those which are merely diagrammatic being executed in a tasty manner. The general get-up of the book is very pleasing.

Correspondence.

A PRACTICABLE SYSTEM OF NOTIFICATION OF INFECTIOUS DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Seaton, Medical Officer of Health for Nottingham, writing on this subject in the *British Medical Journal*, says:—

"If I understand Dr. Mahomed's resolution aright, the proposal" (adopted by the meeting of the British Medical Association at Worcester) "is, that the sanitary authorities should be empowered to require every householder to notify ...and no more....I have heard this idea expressed before, but have never known it to be definitely formulated."

For a definite formulation of this idea, I beg to refer Dr. Seaton to the Bill introduced last session into the House of Commons by Mr. Meldoun, M.P., on behalf of the Irish Medical Association and the Dublin Branch of the British Medical Association, of which Bill I have the pleasure to send him and you copies.

I submit that it is the only measure which promises to effect notification without putting the physician in a false position; and I would urge its general adoption as a means of resolving the existing contention between sanitarians and the profession.

The Bill proposes—

a. To make the custodian of the patient, primarily, solely responsible to notify. He shall find out the nature of the disease in any way he pleases (through the family doctor, if he has one—through the parish doctor, if he has not); but he

must cause notification to be made *per alium aut per se*, and shall be answerable to the sanitary authority if he omits to do so.

3. But he may use the doctor as his agent if the doctor *pleases*; and, in that case, the entire responsibility and penalty shifts at once to the doctor's shoulders, who undertakes to notify, and receives the fee.

Let me point out how this system would work. The child of A. falls sick. Thereupon, he sends for the doctor. Why? Because he knows that, whether he does so or not, he himself must notify—that he will not escape sanitary inconveniences by excluding the doctor, but that, on the contrary, the doctor can save him much trouble and publicity by notifying for him. The physician visits, diagnoses the disease, informs A. of its nature, and of his (A.'s) responsibility to notify. This the physician does without hesitation, because he is not thereby adding in the least to his patient's troubles, or involving him in any sanitary inconveniences which do not already rest on him.

With the notification fee in view (supposing him to have no other incentive), the doctor informs A. that he is willing to relieve him of all trouble of notification. I anticipate that in nine cases out of ten A. accepts thankfully the relief; whereupon, the doctor fills up his notification-form, hands one part as a voucher to A., posts a second part to the sanitary authority, and keeps the block as his own record.

But suppose A.—fearful of sanitation or negligent of his duties—does not send for the doctor. The nature of the disease is discovered by the sanitary authority either by registration of death or otherwise, and A. is prosecuted. He can have no defence. No question can arise which will require the doctor to go into the witness-box to prove that he did or did not hand a notification-certificate. If the "voucher" be not forthcoming, A. is at once convicted and punished. On the other hand, suppose the doctor undertakes to notify, but neglects to do so, A. is questioned or prosecuted as before. He produces his "voucher"; the doctor is at once made amenable, and cannot plead doubts as to the nature of the disease, because he has already pinned himself to it on the face of the "voucher."

I submit that this system would meet every possible contingency. It would afford no inducement to A. to exclude the doctor, nor any inducement to the doctor to conceal from A. the nature of the disease. It would not make the physician the server of a process in the sick-room (unless when asked to undertake notification), nor the agent of the sanitary authority for the infliction of sanitary inconveniences. Lastly, it would not call the doctor (as the "indirect" method of notification does) to appear as witness against his patient's custodian in the police-court.

You will observe that I do not argue this question as a matter of medical feelings or interests, though I fully appreciate this aspect of the matter. I insist that, in the public interest, compulsory notification by the physician should be resisted, because it must cause—and I assert has caused—concealment of disease; because (with this object in view), it must cause, and has caused, the exclusion of the physician until the patient is dying; because (for these reasons) it must cause, and has caused, rather an increase than a diminution in the zymotic mortality of those towns to which it has been applied.

Yours, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.,
One of the Executive of the Irish Medical Association.

AMPUTATION OF THE SCROTUM FOR ELEPHANTIASIS ARABUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On account of the publication in the *Glasgow Medical Journal* for June, 1882, of a paper read before the Medico-Chirurgical Society of Glasgow, 7th of April, 1882, by George A. Turner, Esq., M.D., C.M., in which he gives an account of 138 cases of amputation of the scrotum for elephantiasis arabum, and since published by him in pamphlet form, I take the liberty of requesting that you will give insertion to the following account (a) of two cases operated on by me in July, 1872, at Apia, Samoa, and which I would have published on my arrival in England in 1873, or soon afterwards, were it not that I could

never learn from Dr. Turner the result, though I wrote to him three or four times. He also promised to have them published but he deferred doing so until now; and it is on account of the discrepancies that exist between his published account and my notes of the two operations as well as his statement impugning the originality of my clamp that causes me to ask this favour from you.

Dr. Turner, in a note I received from him, states that none of my letters ever reached him. That he sent the cases to a friend to have them published, but from some cause or other, they were not published.

He also informs me, in reply to a letter I sent him pointing out these discrepancies, that he can only account for them by the fact that he transcribed his notes into his letter-book, but that the ink became so faded as to make it almost illegible, so that he had to trust a good deal to memory when he wrote out the account of the operation for publication.

I am, Sir, yours, &c.,

G. V. MACDONOUGH, M.D., D.I.H., R.N.

CORONERS AND MEDICAL CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read your article on "Uncertified Crime" in the last number of the *Medical Press* with much interest, and beg to send you herewith a copy of my letter to the *Yorkshire Post* in reply to Mr. Malcolm's remarks, which I shall be glad if you will publish in your columns.

Yours &c.,

EDWARD HERFORD,
H. M. Coroner, City of Manchester.

OFFICE OF CORONER.

TO THE EDITOR OF THE YORKSHIRE POST.

SIR,—The coroner for Leeds appears to have made some remarks upon medical certificates. Though misreported so as to be almost self-contradictory, they are evidently founded in sound misapprehension, which as a coroner of thirty years' standing I trust I may be allowed to remove.

The duty of coroner and those which devolve upon medical practitioners are as clear as common and statute law can make them. The coroner is bound, having no option, on being informed of any case of violent, or non-natural, or sudden, or suspicious death, to summon a jury in order to ascertain, not so much the (medical) "cause" of death, as whether anybody is culpable in connection with it.

By the Registration Act a surgeon who has been in attendance during deceased's last illness, i.e., that of which he died, is bound to give a certificate to the friends, except in those cases which he and every one else knows to be coroner's cases according to the above definition.

The absence of a medical certificate must, therefore, be presumed to be due to the fact that either there was no "medical attendant during the last illness," or that the death was one legally requiring investigation by the coroner. I cannot imagine, therefore, what Mr. Malcolm complains of when surgeons do not certify.

I have been for many years protesting against the system of medical men giving certificates, though they have seen deceased not at all before or since death, or perhaps only once in *extremis*, or when the death is non-natural or out of the course of ordinary disease, in which case the law clearly requires an inquest.

Mr. Malcolm seems to object to the trouble and expense of the performance of his duty as coroner. It would be strange for a stipendiary magistrate to complain of the trouble and expense of dealing with "public house" or "cruelty" cases, often, no doubt, "unnecessary." But the duty of the coroner is also magisterial, clearly defined by law, and therefore not amenable to considerations of trouble or expense.

Mr. Malcolm's complaint is "that unregistered cases take him a great deal of time and trouble to inquire into" unofficially. He has no right *thus* to inquire into any cases which come within the definition of coroner's cases. His duty is only to ascertain that they do come within the rule, and then summon his jury. For a coroner to substitute his own private questioning of witnesses, still less the information he may get from others' private questioning,

(a) The article referred to will be found on page 192 of our present issue.

for the public judicial investigation on oath before a sworn jury cannot be defended, and ought not to be allowed or attempted.

I have shown in a pamphlet I send you that the system of surgeons *certifying* when they ought not to certify cloaks foul play by preventing judicial inquiry. I cannot see how, therefore, the *refusal* to certify or the leaving every case out of the ordinary course of disease to the obligatory inquiry before the coroner can, as Mr. Malcolm seems to suppose, produce "a great amount of undiscovered crime" in Leeds. The giving or refusing to give a medical certificate cannot really affect the coroner's duty in any case.

It is a document given purely for statistical, and not judicial, purposes, and cannot be given in evidence or retained, or often even seen by the coroner.

Yours, &c.,

EDWARD HERFORD.

H.M. Coroner, City of Manchester.

[We have also received a letter from Mr. Malcolm, the Leeds Borough Coroner, in reference to our leading article on "Uncertified Crime" in the last number of the *Medical Press*. Mr. Malcolm explains that the 189 deaths in 1881, and 88 deaths in the first half of this year uncertified by medical men were cases inquired into, but no inquests were held on them, the coroner being satisfied in each case that death occurred from natural causes. But our correspondent continues, "the remark if certificates in such cases were given the jury would not have to be summoned, nor the expense incurred, applied to the case then under inquiry, and others where I had not felt justified in passing them without inquiry on oath in court." As regards the necessity for holding an inquest into every uncertified death, Mr. Malcolm does not agree with his colleague at Manchester, and holds that he is not justified in putting the Borough to the cost, and the family to the annoyance, and the jury to extra labour in cases where there is no reasonable doubt as to a death from natural causes. Such cases occurred in Mr. Malcolm's jurisdiction 143 times in 1877, 154 times in 1878, 174 in 1879, 148 in 1880, and 189 in 1881. The letter concludes with the citation of two instances in which unqualified assistants are employed at dispensaries in Leeds. The points of disagreement between Mr. Malcolm and Mr. Herford are, after all, such as would be completely done away with under a reformed scheme of medical practice; existing irregularities undoubtedly do much to complicate the difficulties under which coroners pursue their duties. A discussion of the subject may lead to good results.—ED.]

THE SCOTCH LICENSING AND IRISH GRINDING TRADES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The Governor and Court of the Apothecaries' Hall will be much obliged by your having the accompanying communication inserted in your next issue.

I am, yours truly,

C. H. LEET, M.D., Sec.

The Apothecaries' Hall of Ireland,

Dublin, 1st September, 1882.

"The Apothecaries' Hall of Ireland,

"Dublin, 1st September, 1882.

"The attention of the Governor and Court of the Apothecaries' Hall of Ireland having been directed to the evidence given by Mr. Stoker before 'The Royal Medical Commission,' and commented on in your issue of the 30th ultimo, and which reflects injuriously upon the professional examinations of the Hall, the Governor and Court,

in refutation, do not hesitate to affirm that the general purport of Mr. Stoker's evidence is partial and misleading, and contrary to the recent Report of the Visitors appointed by the General Medical Council to inspect the examinations of the several medical corporations of the United Kingdom."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Owing to some misapprehension of which I am become aware, I request your permission to state that I am not the "Doctor William Stoker, of Dublin," whose evidence before the Medical Acts Commission is referred to in your issue of August 30th.

I am, &c.,

WILLIAM THORNLEY STOKER,

Prof. of Anat. and Member of Council,
Royal College of Surgeons, Ireland;
Surgeon to the Richmond Hospital,
and to Swift's Hospital; formerly
Surgeon to the City of Dublin Hospital.

16 Harcourt Street, Dublin,

September 2nd, 1882.

Medico-Legal Intelligence.

PROSECUTION FOR FORGERY OF PRACTITIONER'S NAME TO CERTIFICATE OF DEATH.

At the Thames Police Court, on September 2nd, before Mr. Lushington, William Henry Viner, of 123 St. George's Street, E., appeared to answer a summons issued at the instance of the Medical Alliance Association, charging him with the wilful forgery on the 21st August of a certificate concerning the death of a child named Annie Niendorff. Mr. C. J. C. Pridham, solicitor to the Association, appeared for the prosecution, and Mr. Beasley, barrister, for the defendant.

Mr. Beasley took a technical objection to the summons on the ground that no one but the Superintendent Registrar of the district had the power to issue same under the Act, but after a lengthy argument from the learned gentlemen engaged, it was over-ruled by the magistrate.

The facts of the case as proved disclosed a very serious offence, and Mr. Pridham in his opening stated it was the gravest charge of the kind in which he had ever been instructed to prosecute. It appeared from the evidence of the mother that the child Niendorff fell ill about the 17th or 18th August, and was taken by her to a medical hall and dispensary at 123 St. George's Street, E., kept by the defendant in the name of a registered practitioner named Berdoe. The child was seen there on two occasions by the defendant, who represented himself to the mother as being properly qualified, and whom the mother believed to be Dr. Berdoe, as that name appeared over the door. On the 21st August the child died, and the mother applied at the dispensary for a certificate of its death. The defendant thereupon wrote in the mother's presence a certificate, in which he stated he had attended the child Niendorff, certifying the cause of death as pneumonia and convulsions, and signed the name of Edward Berdoe, M.R.C.S., L.S.A., 123 St. George's Street, E., and gave the same to the child's mother.

Formal evidence was given by the district registrar of the receipt of the certificate from the mother, and of his having entered the death in the register as certified by Dr. Berdoe.

Dr. Berdoe was then examined, and stated that he had never seen or attended the child Niendorff, or certified the cause of death. The signature to the certificate was a forgery.

In cross-examination by Mr. Beasley the witness stated he had sold the business of a chemist at one time carried on by him at 123 St. George's Road, E., in connection with his medical practice, to the defendant in October, 1880. Since that time his connection with the place and the defendant had entirely ceased. He had desired the defendant on several occasions to remove his name from the fascia, which he promised to do, and witness believed it was done, and he was unaware until so informed by the solicitor for the prosecution that his name still remained up there. He had

never given the defendant on any single occasion any authority to act for him or to use his name. The defendant had made overtures to him to attend on the premises and see patients, which he declined.

Mr. Lushington, in giving judgment, said the defendant had committed an offence of a most serious kind. It had been suggested by the defendant's counsel that he had no power to deal with the summons. He felt some difficulty in doing so, not on the technical ground which Mr. Besley had put forward, but because he was in some doubt whether he ought not to commit the defendant for trial. However, as he had not been requested to do so by the prosecution, he should impose the severest penalty he had power to inflict under the Act. He ordered the defendant to pay a fine of £10, and £5 5s. costs, or to be imprisoned for three months in default.

Dr. Berdoo applied to the magistrate to compel the defendant to remove his name from the premises. Mr. Lushington regretted that he had not the power to do so, but advised Dr. Berdoo to consult a solicitor.

Obituary.

CHARLES MOREHEAD, M.B., C.I.E., F.R.S.E.

INTELLIGENCE of the sudden death of Dr. Charles Morehead, late of the Bombay Medical Service, which took place a few days since at Redcar, Yorkshire, will be learned with regret among that large circle of acquaintances he was known to possess. Dr. Morehead was the son of the late Rev. Robert Morehead, D.D., rector of Easington, Yorkshire, and entered the Bombay Medical Service in April 1829. From 1835 to 1838 Dr. Morehead was on the staff of Sir Robert Grant, Governor of Bombay, having in the former year been elected President of the Medical and Physical Society of Bombay, a position he held until 1859. In 1838, on the death of Sir Robert Grant, he was appointed surgeon in the European and Native General Hospitals, and in 1845 became the first Principal and Professor of the Principles and Practice of Medicine in the Grant Medical College, Bombay, established to give the natives of Western India the benefits of a professional medical training; continuing in that capacity till 1859, when he took a sick furlough to Europe, and finally retired from the Bombay Service on the 30th June 1862. In January 1860 he became Surgeon-Major, and on the 6th September 1861 he was appointed an Honorary Surgeon to the Queen. Deceased was an M.D. of the University of Edinburgh, a Fellow of the Edinburgh Royal Society, and in 1881 his services in the cause of Indian education were acknowledged by his being created a Companion of the Order of the Indian Empire. As an author, Dr. Morehead was known for works treating of the diseases of Europeans in India, and his Practice of Medicine is still an authority on the subjects on which it treats. He also wrote a life of his father. At the house in Manor Place, Edinburgh, where he spent his later years of well-earned leisure, Dr. Morehead was wont to receive many visitors, who found in him a genial friend, none of whom will be prepared to hear of his sudden death at the age of 75.

A Specific for Ophthalmia.

AN infusion of the curious scarlet seeds of the *Abrus precatorius* has long been used in the interior of Brazil as a popular remedy in the treatment of ophthalmic disorders. In some experiments made by Dr. de Wecker (*Comptes Rendus*) to test the action of this remedy he found that a weak cold infusion, made from the powdered seeds, when applied as a lotion, rapidly produced a purulent ophthalmia of intensity corresponding to the number of applications made. The factitious ophthalmia thus produced disappeared in the course of ten days or a fortnight without any therapeutic intervention or danger to the cornea, and Dr. de Wecker is of opinion that this property possessed by the seeds of provoking a very intense ophthalmia of short duration could be utilised in ocular therapeutics in the treatment of granulations, conjunctival diphtheria, &c. The leaves of the plant are also used in the East as a remedy in croupal cough.

Isolation in the Paris Maternité.

M. TARNIER, in a letter recently addressed to the Soc. Médic. des Hôpitaux, recalls the very extraordinary results obtained by isolation, the use of antiseptics, and all means proper to ward off contagion. In the new pavilion he has had constructed, in which each chamber can only be entered by a separate door opening outwardly, without any aperture toward the hospital except a single large pane of glass let into the wall, permitting the surveillance of the patients, he has had but six deaths in 1,200 cases of labour. Within the past few years even there have been 600 cases without a single death. No statistics ever published have shown such favourable results as those of M. Tarnier.

PASS LISTS.

Naval Medical Department.—The following is a list of the successful candidates for appointments as surgeons in the Royal Navy at the competitive examination at Burlington House on 21st August and following days :—

Marks.		Marks.	
Logan, J. S.	2,060	Martin, J. McC... ..	1,850
Lawson, R. J.	2,030	Bagnall-Oakeley, J. L. ..	1,770
Cashin, J.	2,025	Woore, F.	1,765
Nunan, T.	1,980	Craig, W. M.	1,740
Norman, W. H.	1,970	Jackson, H. 3.	1,700
Todd, P. E.	1,960	Phillips, J. M.	1,605

In addition to the above, eight other candidates were reported by the examiners as qualified.

Army Medical Service.—The following is a list of candidates who were successful for appointments as surgeons in Her Majesty's British Medical Service at the competitive examination in London on the 21st of August, 1882, and following days :—

Marks.		Marks.	
Macpherson, W. G. ..	2,305	Stuart, J. R.	2,015
Simmons, R. J. S. ..	2,305	Morse, T. R.	1,975
Reid, F. W.	2,233	Deeble, W. B. C.	1,960
Phipps, E. V. A.	2,180	Prendergast, J. M. ..	1,885
Hunter, V. E.	2,160	Bond, R. P.	1,905
Baird, A.	2,155	Stewart, J. McD. ..	1,890
Hamilton, T. W. O'H ..	2,065	Thomas, G. T. H. ..	1,870
Sample, D.	2,030		

Indian Medical Service.—List of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House on the 21st August, 1882, and following days :—

Marks.		Marks.	
Leahy, A. W. D.	2,980	Davis, R. E. S.	2,840
Webb, W. W.	2,850	Fuller, H. K.	2,820
Weir, R. R.	2,510	Neilson, W. H.	2,510
Burke, W. H.	2,377	Crimmin, John	2,185

Thirty-nine candidates competed for eight appointments. All were reported qualified.

Notices to Correspondents.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. AINSLEY.—The late Professor Balfour was not a member of the medical profession. He was, in the fullest sense of the term, a "scientist," following the branch of biology, and in his later researches, confining himself more especially to embryological inquiries. The subject on which he would have lectured is "Morphology," and, in one sense, it is a new science, but new only because later investigations have enabled form and life to be given to its details. We do not judge you or any correspondent in the way you suppose. You can write freely, and if possible we will assist your endeavours.

DR. T. KING CHAMBERS (Sunningdale).—We will endeavour to obtain the information from one or two independent sources.

DR. C. (Manchester).—The gentleman's name referred to was removed from the *Register*, but it was subsequently replaced, upon explanations being given, which were considered satisfactory. We believe he was sinned against rather than sinned, and has, we understand, since conducted himself as a man of honour and a gentleman.

INEBRIATE ASYLUMS.—"Nemo" asks for any institution, exclusively Catholic, for the voluntary control of habitual drunkards. Preferable if in Ireland.

[There is no institution in Ireland for the voluntary control of inebriates, nor is there in England any such institution exclusively Catholic; but, if desired, we can supply our correspondent with the addresses of the very few inebriate asylums in England.—ED.]

INQUIRY.—Dr. Walter G. Smith has not published any work on Diseases of the Skin, but has contributed several papers on the subject, as follows:—1. *Dublin Quarterly Journal of Medical Science*, Nov. 1871. "Analyses of 1,100 Cases of Skin Disease." 2. *Dublin Journal of Medical Science* (new series of preceding), May, 1875. 3. "Notes on Diseases of the Skin," Nov., 1878. "On Molluscum Sebaceum," 1879, March and Dec. 4. "On Chrysophanic Acid." 5. "On Favus," 1880, Feb. and Nov. 6. "Warty Growths on Vulva." 7. "Vesicular Disease of Hands," 1881, Jan. and May. 8. "Herpes Gestationis." 9. "Treatment of Diseases of the Skin" (*Acro*), *British Medical Journal*, May, 1880. 10. "Nodose Hair," *Trans. International Medical Congress*, 1881. 11. "Dipterous Larvæ in Skin."

ALOYSIUS.—A very small man, but the "author" of a very large book. Your conclusion is perfectly justified by appearances, and is in a measure no more than a reflection of that to which we had been conducted. There is little merit in such a performance, but it is an excellent advertisement, and as such it doubtless fully serves the end held in view. We would not advise your emulating the example it affords.

COUNTRYMAN.—You are too severe on your opponent. Would it not have been as well to have availed yourself of another opportunity of expressing your opinion? From your own showing the means of doing so are not unfrequent. As it is, you have plainly put yourself in the wrong, and the only way to regain the position you have forfeited is by making ample apology for the inexcusable conduct you were guilty of. It may not be a palatable proceeding; it is, nevertheless, the only one compatible with the feelings of a gentleman.

R. C. SLANE (District Medical Officer) asks whether he is bound to attend to visiting tickets sent through the post without any information regarding the nature of the case?

[By the second section of Article 21 of the Dispensary Regulations the medical officer shall duly and punctually attend at the house of the party on whose behalf application is made, or elsewhere, as the case may require, and supply all requisite medical and surgical advice and assistance to every poor person in the district or division of a district under his charge. This rule is, however, defined by notice, which is posted at the dispensary, which states that visiting tickets for the attendance of the medical officer at the patient's home may be presented to the medical officer at the dispensary, or may be presented to him or left for him at his residence, or may be presented to him personally anywhere. Tickets presented at the dispensary should be presented between the hours named, and tickets presented at the medical officer's residence, or elsewhere, should be presented as early in the day as possible. It is therefore obvious that such a ticket, to be valid, must be "presented" to him, or left for him at his residence, or presented to him personally anywhere, and we do not believe that delivery by the postman is presentation within the meaning of the rule. We, however, counsel our correspondent to attend the patient, and then remonstrate against the postal system.—ED.]

DR. FOURNIER'S "Diagnosis of Locomotor Ataxy of Syphilitic Origin" received, and shall appear in an early number.

MR. T. HARR.—The request is a most unreasonable one, and should never have been made.

SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me if I am right in believing that medical officers of rural Poor-law districts in England are entitled by law to a retiring pension upon the basis of the rule laid down in the circular letter of the Local Government Board?

Kindly also refer me to the Act of Parliament or order of Treasury (or other order) by virtue of which a claim to such pension can be sustained; and say to whom application for it should first be made.

Yours faithfully,

SENEX.

[*] Unfortunately the Poor-law Medical Officers' Superannuation Act (England), like that which holds in Ireland, of which it was the sequence, is simply permissive, *id est*, Boards of Guardians may give or withhold superannuation allowance according to their own idea of the fitness of things. Our correspondent appears to be quite unconscious of the requirements of the Act, which necessitates that the applicant should be at least 60 years old; that he should have held office twenty years; that he is incapacitated by bodily or mental infirmity; that proof of which must be subscribed to by the Poor-law inspector of the district to which the medical officer belongs; that he must resign his office ere making application; and that such application must be communicated to the whole Board, who must be spe-

cially summoned to consider the same. The truth is, the Medical Officers' Superannuation Act is so beset with difficulties, and the chance of getting anything or nothing is so doubtful, that unless the Act be amended it is questionable whether the same be a boon or otherwise. We cannot but think that medical officers are themselves mainly to blame. "Jupiter helps those who help themselves." Has our correspondent done aught to help on this much-needed reform? —ED.]

RESIDENT PUPILS.—No. 99 asks:—"Do Dublin surgeons in good practice, and connected with good hospitals, take into their families young men and guide and tutor them until they pass the Dublin College of Surgeons? And if they do, what are the usual terms?"

[A few hospital surgeons do so, and the terms are usually £4 4s. or £7 7s. per month for board and all accommodation, except washing. An advertisement in our columns will, no doubt, elicit answers.—ED.]

DR. WHALLEY (Bewdley) will please receive our best thanks.

REQUESTS BY PATIENTS TO THEIR MEDICAL ATTENDANTS.—It is not often we have to chronicle acts of practical gratitude in this direction. We are, however, pleased to notice an exception in the case of the Marquis of Conyngham, lately deceased, whose will was sworn last week under a personality of £118,000. In it the deceased nobleman has bequeathed to "his friend," Mr. Edgcombe Venning, F.R.C.S., of Sloane Street, Brompton, £200; and a like sum to his resident medical attendant, Mr. Robert Hippisley Cox, M.R.C.S.

H. McH. says:—Having made inquiries from the Secretary of the Local Government Board for Ireland if the holder of the licence of the Society of Apothecaries, London, would be accepted as an apothecary under said Board, the following was the reply:—"That the opinion of the Board is that any legally qualified apothecary for Ireland may be appointed to the office of apothecary under the Local Government Board." Please say in your Correspondence column if the holder of the above licence would be eligible from the reply above referred to.

[Under the 31st Section of the Medical Act any registered practitioner, including a L.S.A., may practise in any medical capacity or as an apothecary in any part of the Queen's dominions, notwithstanding any Act to the contrary.—ED.]

Vacancies.

Chichester Infirmary.—House Surgeon and Secretary. Salary, £100 with board and lodging. Applications to be sent to the Secretary on or before Sept. 9th.

Cookstown Union, Fomeroy Dispensary.—Medical Officer. Salary, £100, and £20 as Medical Officer of Health. Election, Sept. 11th.

Downpatrick Union, Portaferry Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 20th.

Mitchelstown Union, Kildorrery Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 13th. (See Advt.)

Northampton General Infirmary.—Physician. Applications to be forwarded to the Secretary not later than Oct. 27th.

Northleach Union.—Medical Officer. Salary, £27 10s., with the usual extra fees. Also Medical Officer of Health. Salary, £100. Applications to be sent to the Clerk not later than Sept. 12th.

Appointments.

COATES, W., M.R.C.S., Resident Accoucheur to the London Hospital. CRESSWELL, NATHANIEL ENGELHEART, M.D. St. And., M.R.C.S., Medical Officer for the Bilsborrow District of the Towcester Union.

HOLLAND, JAMES C., L.R.C.P.L., L.F.P.S. Glas., Medical Officer to the Dungarven Dispensary District of the Dungarven Union.

LAING, E., L.R.C.P. Ed., M.R.C.S., Medical Officer of Health for the Cowpen District, Blyth Northumberland.

PEARSON, THOS. FRED., M.D. Brux., L.R.C.P.L., M.R.C.S., Medical Officer for the Midland District of the Midhurst Union.

SPENCER, WALTER, M.R.C.S., Medical Officer for the Gringley District of the East Bedford Union.

VISE CHRISTOPHER, M.B., M.R.C.S., House-Surgeon to the Infirmary, Tunbridge Wells.

WAINWRIGHT, CHARLES HENRY, M.R.C.S., Medical Officer for the Howden District of the Auckland Union.

Marriages.

HOWE—LE FEAUX.—August 30th, at the parish church, Llanidloes, Jonas Howe, L.R.C.S.E., of Llanidloes, to Emma Elizabeth, youngest daughter of William Le Feaux, Esq., Penrill House.

PAYNE—MACPHERSON.—September 2nd, at St. Mary Abbott's, Kensington, J. F. Payne, M.D., Assistant-Physician to St. Thomas's Hospital, London, to Helen, daughter of J. A. Macpherson, of Umina, Melbourne, and of Baywater, London.

Deaths.

BOWEN.—September 2nd, at Harrow-on-the-Hill, F. Perry Bowen, M.R.C.S., aged 86.

DOLTON.—August 19th, at Lee Road, Blackheath, S.E., William Blucher Dolton, M.D., aged 68.

REDMOND.—August 26th, at Drumannon, near Portadown, John Redmond, M.D., Q.U.I.

ON THE ETIOLOGY AND TREATMENT OF A CERTAIN FORM OF ENDOMETRITIS, ACCOMPANIED WITH VERY TENACIOUS LEUCORRHOEA. (a)

By C. H. F. ROUTH, M.D., M.R.C.P.,

Consulting Physician to the Samaritan Hospital for Women and Children, &c.; Fellow of University College, London.

THERE is a variety of dysmenorrhœa which we occasionally meet with, and which is very difficult of cure. I allude to that form where, in addition to the pains about the uterine organs, to be hereafter more fully defined, there is a thick muco-purulent discharge, so sticky, that it is often well nigh impossible to remove it.

The general symptoms of this affection resemble in many respects those I detailed in a paper read before the Obstetrical Society of London (*Transactions*, vol. xii, 136), on Fundal Endometritis, and vary according to the part of the uterus affected. To recapitulate a few particulars. First, the pain felt varies greatly; it is sometimes trifling, general uneasiness being the chief complaint, with the knowledge of the daily passage of more or less leucorrhœal discharge, which becomes yellow on the linen. More frequently, however, there is a marked feeling of weight in the uterus with bearing down; and the symptoms are greatly aggravated at the menstrual period, when colicky uterine pains are superadded. These, beginning in the back, run downwards towards the region of the round ligaments, and outside one, generally the left, or both thighs, coming on in paroxysms more or less severe. It has been stated that in such cases there is no rise of temperature, even although the pain has been excruciating, leaving no trace when once the cause has been removed. This, I am satisfied is an error. If the temperature be taken in the axilla, it is true there is seldom any rise of temperature. If, however, it be taken in the vagina, it will be found raised sometimes to 103°. This, however, is by no means an exceptional case. In

most, if not all, women during menstruation the temperature rises in the vagina.

To what is this particular discharge due? First, I believe, in most cases, it is essentially the result of gonorrhœa communicated during the first few days of married life, whether by a gonorrhœa proper or a gleet. At least, in questioning many women, they always referred its occurrence to marriage; and in not a few of these cases, when I have been able to examine the husband also, I have found gleet. Yet, even here, I have observed what appears to contradict this view. I have found gleet present in a husband, and no sticky discharge in the wife.

If we closely question the wife, however, in these cases, we often are enabled to learn that soon after marriage, indeed within the first week, some acute symptoms supervened; abdominal pain low down, over both ovaries, especially the left, and in the groin, with more or less feverish excitement. In one case, I believe, peritonitis was the immediate result, which proved rapidly fatal. In another case, the peritonitis was more limited, and recovery occurred. Now, in both these cases the wives were believed in the first instance to be healthy; but both husbands were affected with acute gonorrhœa. The opinions of Noeggerath, and his belief that catarrh of the Fallopian tubes plays a part in the occurrence of perimetritis, and even peritonitis, have been widely made known. By most gynecologists, they have been said to be extravagant. Attention has also been called lately to this etiology by Dr. Edis. I must say, for myself, that, while I cannot go quite to the length of Noeggerath's opinions, I am quite sure that the chronic form of tenacious uterine leucorrhœa with dysmenorrhœa, of which I am now speaking, is due to gonorrhœa in most cases. In a few more cases, it is due to intense vaginitis in the virgin, which acts precisely in the same way in producing tenacious uterine leucorrhœa; a vaginitis capable of producing a gonorrhœa in the male, or rather an urethritis, which cannot be distinguished from gonorrhœa.

Whatever be the cause, however, in nearly all the cases where the discharge existing is thus tenacious, I

(a) Read before the British Medical Association at Worcester, August, 1882.

assert distinctly also that, so far as my experience goes, sterility is the constant result. The affection, is moreover, in many cases, perhaps the majority, exceedingly difficult of cure, and for this simple reason: it is not only the uterine cervical and superior cavity which is affected, but the tubes likewise. A temporary cure by local applications to the uterus may be effected in the cavity, and for a few days a practitioner may believe he has cured the patient. Perhaps, a fortnight later, he is mortified in finding his patient as bad as ever. There has been no cure of the catarrh of the Fallopian tube, and, through the continuity of surface, the uterine mucous membrane has been affected.

I believe one of the reasons why peritonitis is not more common in these cases is that the expulsive or downward action of the cilia of the tube directs the unhealthy secretion into the cavity of the uterus rather than into the peritoneum.

I think it will facilitate the description of the points I wish to bring especially before your notice if I speak of this disease under three varieties, although they are but stages of the same disease—namely, 1. Where it is confined to the cervix; 2. Where it extends to the superior cavity of the uterus; 3. Where it reaches the Fallopian tubes and peritoneum.

1. Let us speak first of the cervical variety. On examining a woman affected with this form of tenacious leucorrhœa we generally find an accumulation of mucus around the cervix. This is generally removed with difficulty; but even then a more or less thick cord of the same secretion projects as a piece of string from the os, and cannot be detached. Even if a piece of thick wire or a sound, around which some medicated cotton has been wound, be introduced into the uterus, it cannot be so removed. More and more seems to have accumulated above, and the mucus is as tenacious as ever. It is rare, however, that in such cases the operation can be done without exciting pain just as you pass the internal os, and sometimes higher up. The severity of this pain varies. In more chronic cases it may be slight; in others, and in these generally the dysmenorrhœa is very troublesome also, it amounts to an agony, which lasts for hours afterwards. I may here state, however, as useful, not only in these cases, but in others where the passage of the sound is attended with pain, that the injection, *per vaginam*, of water as hot as the patient can properly bear it, is the most effective way of checking or relieving it. The moment the internal os is passed, the exact pains which the patient is accustomed to have during a period are reproduced. The patient, indeed, will spontaneously exclaim, "Oh, you are bringing on all my poorly pains!" The point of starting the pain is, therefore, probably at the internal os. I have also noticed that in a large proportion of cases uterine version or flexion exists, especially anteversion; but there can be no doubt that the internal os, by reason of the pain, is the seat of spasm, which, for a time at least, precludes the passage of the cervical fluid into the superior uterine cavity. This spasm, as well as the version where it exists, is in a measure a preservative action, and often prevents the development of the second stage.

If we now look to the mechanism of the production of this affection, we may trace some of the concomitants which render it so permanent, especially with married women, or women having relations with men, and which make it so obnoxious to treatment. These are mainly two:—1. Direct suction upwards of the diseased fluid by the uterus; 2. The natural pressure downwards, and partial opening of the os during copulation.

I have elsewhere shown that, by means of a very simple instrument, we may prove that there exists a power of suction upwards by the vagina and uterus during expiration, which is entirely due to atmospheric pressure. Take an ordinary speculum; close the uterine end by a thin membrane, and the other end by a cork through which a glass tube bent at right angles passes, and which is of some length; if this speculum be filled with water,

which is allowed to extend also up the tube, at each inspiration the patient makes the water will rise in the tube, while with each expiration it will fall—i.e., there is a fall of the water in the tube. The mechanism of this change is too obvious to require comment. In some women, owing possibly to some peculiar folds of the mucous membrane of the vagina, which acts in a valvular manner, air is being continually sucked up, and at last fills the vagina till it provokes an expulsive effort, and the air is forcibly propelled outwards, and sometimes with a noise similar to flatus expelled *per anum*. I believe it is an operation very analogous to this which takes place *in utero*, through some condition, also of a valvular character, in the external os which causes vaginal fluids to enter into the uterus during expiration. It is, perhaps, for this very reason that, at the critical moment of the orgasm induced by sexual intercourse, repeated and sudden expirations occur, which facilitate the upward passage of the semen into the uterine cavity.

Dr. Matthews Duncan has referred this suction upwards of vaginal fluids *in utero* rather to a reverted action of the muscular fibres of the uterus; and in this manner he explains the occasional drawing upwards of intra-uterine pessaries and their enlarged discs at their distal end right up into the uterus, which often taxes disagreeably the practitioner's ingenuity to get them out again. I have also had some of these unpleasant accidents to meet. Nor is this confined to the uterus. In cases where an artificial anus has been made, I have seen large pieces of lint and cotton sucked up and disappear altogether, and never found again. Nay, more; when an anus was made in the groin, and an ivory tube with a large cap placed in it, this has also been sucked up and disappeared. In one case where this occurred, the patient is still living. Here, perhaps, there may be some reversed peristaltic action to account for it. Still it seems more rational to attribute, at least in the uterus, these effects rather to propulsion upwards by atmospheric pressure during expiration: first, because it necessitates the dilatation of the external os, which would imply an uterine contraction, which, we should suppose, would expel the contained intra-uterine pessary; and, secondly, because the uterine cilia have also an action in the expulsion of contained fluids. The moment, however, we explain it by atmospheric pressure forcing fluids upwards during expiration, and some accidental valvular action of the mucous membrane at the os uteri, the result is obvious. That such valvular action of folds of the mucous membrane does take place, is often made sufficiently palpable; but, conversely, when we try to introduce a sound, in some cases, we are prevented altogether by some fold of mucous membrane, and also by the result often noticed, and well instanced by Dr. Barnes, that, when the external os is cut a large quantity of mucus, previously retained, obtains at once a free exit.

There is another cause also operative in such cases; the fact that, during intercourse, the uterus is forced downwards to meet the male organ, and probably the os undergoes a sort of dilatation at the same moment, both of which circumstances mechanically facilitate passage of acid fluid upwards in the uterus. The way in which gonorrhœal fluid may thus pass into the uterine organ is sufficiently obvious.

Be it, however, gonorrhœal or other acrid vaginal fluid, it is equally obvious how, once in the cervical cavity, it will act as an irritant. It is well known that the vaginal secretion is acid, sometimes intensely so, whereas the uterine secretion is alkaline and markedly so. When an excess of acid fluid is thus sucked up *in utero*, of itself it will produce irritation leading to inflammation of the mucous membrane; and secondly, the contents of the uterus, now being acid, will kill any spermatozoa which are present, and so sterility follows as a matter of certainty. In these cases, the dysmenorrhœa is mainly due to obstruction at the external os, and the pain is chiefly referred to the lowest parts of the pelvis.

It was the examination of many of these cases that led

me to conclude that, in a large proportion, the fluid sucked up did not pass the internal os, but was by constriction there prevented from going beyond. I have been met by the statement that there are no special circular fibres here forcibly to close the opening. All we notice are merely a few fibres which here decussate. I do not in any measure question the anatomical fact. But I am certain it is not a pathological fact. Like muscle everywhere when frequently taxed, it becomes hypertrophied, and then it acts distinctly as a sphincter. I have verified this over and over by the use and retention of caoutchouc intra-uterine pessaries, where at this point there has been left a very distinct circular impression. And more than this, such constrictions may under disease take place elsewhere within the uterine cavity, especially in certain forms of version or flexion, as these tubes prove. This is possibly sometimes the seat of ulceration, a state of things being here produced which is analogous to fissure of the rectum; as, when touched with the sound, not only is the pain intense, but blood follows its use.

Certain it is, however, that constriction does occur at the internal os, and here we have the explanation of the intense pain sometimes experienced by women. As you pass the sound through the internal os you at once provoke a spasm, which continues for a time, and not unfrequently you find your sound comes out bloody, exactly as it does in some cases of stricture of the male urethra, so forcible has been the local resistance. It may be that there may also exist at such parts slight ulceration.

2 Sometimes there is not such a complete closure or resistance at the internal os, or the cervical cavity is so full and dilated with muco-pus, that the fluid, not being expelled downwards, is forced up into the upper uterine cavity of the uterus, and we have the second variety of tenacious gonorrhœal uterine leucorrhœa. Sooner or later this result follows, and gradually but completely the uterine cavity becomes filled with fluid. The symptoms now are altogether different. They are, in a few words, those of greater and higher local uneasiness; sometimes phenomena of spurious pregnancy, followed often by symptoms not unlike those of miscarriage; but I shall again refer to them. Exacerbation of pain recurs not only at the onset of menstruation, but at other times, when the contained fluid, whether catamenial during menstruation, or muco-pus during the interval, is forcibly expelled by a powerful uterine contraction which overcomes all before it, and relief follows. Fortunately, the disease does not always extend beyond. But sometimes it does, and then the case is one of very serious import, at least one of confirmed invalidism. This constitutes the third variety, where the Fallopian tubes become inflamed, and even perimetritis may occur. In the worst cases we may have those results insisted upon by Noeggerath, when a few drops of the inflammatory secretion of the tube escape, possibly by a contraction of the tube giving rise to perimetritis, and sometimes rapid and fatal acute peritonitis. Fortunately, in this country at least, this unhappy complication is not common. It cannot be said, at least in Great Britain, if it can be elsewhere, that all our young married ladies are diseased by their husbands, so that young ladies are afraid to be married, because they know that all their married acquaintances were made ill directly and never again recovered.

The dysmenorrhœa in these cases is ver severe, accompanied with general uterine pain, tenderness reaching high up, and very aggravated.

Let us now distinguish how far from symptoms we may diagnose these three different varieties. I have already spoken generally of the general symptoms. We have considerable assistance, as I have shown in my paper read before the Obstetrical Society (*Transactions*, vol. xii., p. 136) "On Fundal Endometritis," by the special localization of the pain which is influenced by the nerve-distribution. In the cervical variety, the pain is referred to the lower part of the sacrum, the lower part of the pelvis, where there will be heavy, dull pain, sometimes reaching as high as the groins, but not higher. The vagina also,

especially at the upper part, feels sore, so that connection becomes sometimes very painful, or, if pressure be made with the finger on the cervix, it gives pain. Once become chronic, however, all these symptoms are greatly diminished in intensity. In the second variety we have pain extending higher up, more marked just above the pelvis and pubes, markedly in the groins, and extending down the thighs, generally the left. Occasionally it extends, as in ordinary cases of fundal endometritis, up to the waist, in the region of the semilunar ganglion, and over both ovaries, specially the left. In the third variety the symptoms are those of perimetritis or peritonitis, which need no special description, except that I may remark that I have noticed in several of those milder or more chronic forms, where neither perimetritis nor peritonitis existed, that on pushing the finger high up on either side of the uterus, or with the index finger placed there, making pressure from the abdomen, I produced intense pain and a sickening sensation even in those cases where there was no enlarged ovary, although in some I have noticed these organs also enlarged and very painful.

So much for the pain. But in the second variety it often occurred that sudden relief was obtained, at least for a time, by a forcible expulsion of the uterine contents by a sort of labour-pain. In these cases also, except where the disease had lasted many years, and sensation, as if it had worn itself out, was diminished, intense dysmenorrhœa was present, and the pains extended higher in the abdomen, according as cervix, fundus, or tubes were affected. I should remark that the breasts not only swell and become uncomfortable in these cases, as is commonly observed during menstruation, but become exceedingly painful, constituting mastodynia, which even persists after the period, and occasionally gives rise to hypertrophy of the organ. In these cases the second variety is always present.

Treatment.—For a long time I was greatly puzzled with these cases. If I cured them for a time, they were sure to recur. It is so even now with a few cases, and especially with those which include the third variety. The principles of treatment indicated here are three-fold; first, local antiphlogistic measures and other general agents to relieve the local congestion or inflammation; second, free exit to all contained irritable fluids, and the prevention of the suction upwards of the same; third, local appliances to correct the diseased action of the mucous membranes, and to keep the cavities patent. It is my conviction that the cases are very few and far between, which will yield unless these three measures be combined; and even in ordinary cases of leucorrhœa of an uterine origin, where the tenacious mucus does not exist, the same treatment is most efficacious.

First, of the local antiphlogistic measures and other general agents to relieve the local congestion or inflammation, blood-letting by means of leeches applied to the cervix uteri is both safe and effective. It is, in fact, a *sine quâ non*, the backbone of success, and much to be preferred, in my estimation, to the lancet. The uterus in these cases is more or less hardened. Fibrinous deposit has, in measure, taken place in its parenchyma, and blood will not flow, though the cervix be pricked heroically and extensively. The hysterotome, or cutting the os on both sides from within, if a knife were used at all, limiting the cut to the cervical cavity, was the best way of doing it. But leeches are to be preferred. The very suction of the leeches brings down the blood, favours the downward course; and, when they fall off, the oozing of blood continues. In a plethoric woman (six leeches at a time), the leeching may be repeated half a dozen times at least. It is the best preservative against subsequent inflammatory complications. If there be also much abdominal pain, then leeches may also be applied on the abdomen; but here I think blisters, or iodine paint applied to the belly, and frequent saline purgatives with anodynes, and alterative doses of mercury, are the best adjuncts.

The patient thus prepared, we are in a position to put in operation the second mode of treatment, viz., to give a free exit to all contained irritable fluids, and to prevent the further upward suction of the same. This, after all, is one of the first principles of surgery. If matter be cooped up in any cavity we must let it out. If the external os be small, and its action valvular, as before explained, it must be cut through. Mere dilatation, without a bougie or intra-uterine pessary, at best can only have a temporary effect. Nor have I ever seen the slightest danger occur from cutting the external os in a patient previously prepared by the measures before indicated. A pair of scissors, a bistoury, or Dr. Barnes's instrument, is sufficient. Precisely as when we cut a fissure in the anus, the parts are at rest. No more suction can take place upwards, and a free exit is given to all contents. We have, in fact, one abscess with a free external opening. The cervical cavity can now be locally treated by local agents, and its diseased action cured. A number of these are in daily use. A small stick of nitrate of silver may be advantageously left in the cavity, which will often correct and change the acrid secretion, and recovery may follow. Another agent is pure carbolic acid, placed on a piece of wire previously covered with cotton-wool, and afterwards dipped in crystals of iodoform. This last is very successful, and, moreover, relieves pain. I have sometimes used iodine paint, as advised by Dr. Wynn Williams, made by mixing iodine, iodide of potassium, water, and spirit, in equal parts; but I have not found in my practice anything as a local agent so successful as the iodoform and carbolic acid conjoined.

When, however, we have to treat the second variety of this disease, we tread upon more dangerous ground. It should be stated unequivocally that, if local remedial measures, such as the hysterotomy and intra-uterine pessaries, be employed before full and effective antiphlogistic regimen has been premised, inflammatory complications of serious character, and death by septicæmia, may follow. If this regimen, however, have been observed, it is comparatively safe to cut the internal os by the hysterotomy, or dilate by a sea-tangle or sponge-tent. The morbidly contracting decussator fibres of the internal os must be overcome. If we cut, it is wise to let the patient bleed awhile. If the bleeding seem too profuse, then it is wise to introduce a small piece of sea-tangle; but one important caution should be remembered. It should not be straight; it should have the exact curve of the uterus. To attempt to put a straight one in mars and injures the cut position, and is favourable to the development not only of severe pain, but of inflammation. For this purpose I invariably use sea-tangle of various curvatures; or if I use a sponge-tent, I pass through it a piece of steel wire, which I then bend to the curve required. Sometimes, by pulling down the uterus a little way, the tangle or tent is more easily introduced. But the uterus should not be pulled down far or violently, for peritonitis may be the result. Be it tangle or tent which is used, another precaution is necessary. Surround either by a little cotton-wool, and dip it in a solution of glycerine and iodine. This is an antiseptic agent which prevents subsequent poisoning.

Sometimes, however, notwithstanding every care, the pain produced is so great, that neither tent nor tangle can be borne. We must then proceed another way. If the pain and bleeding persist, inject into the vagina water as hot as the patient can bear. This almost invariably arrests them both. If the bleeding persist, then I plug the vagina only. An anodyne suppository helps the patient, if used in addition. Within forty-eight hours, all plugs being removed, I then insert into the uterus a small taper, such as I show you; it is covered with cotton, shaped to the cavity, dipped then in carbolic acid, introduced, and left *in utero* for about twelve hours. It is seldom that this process need be repeated. The uterine tenderness generally disappears, and a

large sound can be introduced without pain. The case may be left then, and will often do well; but I prefer using an intra-uterine pessary, one of the various forms I now show you, and which are for the most part well known to the profession. I have kept in the caoutchouc ones I show you for a year; the combined Hodge's and intra-uterine pessaries which I described at Bath before the Association, for six or eight months. The mucous membrane then assumes a healthy character. The catamenia are copious and painless often from the very first, generally by the third subsequent catamenial period. The dysmenorrhœa and the tenacious uterine leucorrhœa alike disappear.

Lastly, as regards the third variety; in the more acute forms, the antiphlogistic treatment should be fully and heroically carried out at the onset, if we be fortunate to see the case early. Local leeching to the cervix and over the abdomen, followed by blisters, are here indicated; but even general bleeding should not be feared if there be much pain. Calomel and opium in half-grain doses should be given every three hours; and five minims of tincture of aconite, two drachms of liquor ammoniæ acetatis, for every two hours, till temperature and fever abate. This treatment may prove effective. More often, however, the disease assumes a chronic form.

I have noticed that, in cases where the early symptoms have been of this serious import, once the chronic symptoms have occurred, the treatment recommended for the second variety has altogether cured the disease; possibly by insuring a free exit of the contents, possibly because the intra-uterine pessary, if *in situ*, precluded the influence of atmospheric pressure of suction upwards; possibly because an uterine pessary always favours a copious flow of catamenia, and thus relieves all local congestion. And what is more agreeable to the sufferer, the matrimonial alliance, which had hitherto proved an occasion of sorrow by the disease produced, has passed into one of joy through the birth of a child.

THE EXPEDITIONARY FORCE FROM INDIA TO EGYPT IN 1800.—II.

By Surgeon-General C. A. GORDON, M.D., C.B., Q.H.P.

CONTINUING remarks already made in the *Medical Press and Circular* on the Indian expedition to Egypt in 1801, it is well for statistical purposes to give the numerical strength of that force. The first portion of the contingent sailed from Bombay on December 23, 1800, but did not reach Suez until the end of April, 1801, this great delay having been due to adverse winds in the Red Sea. Shortly afterwards the remaining portion of the force followed, and was joined by artillery, cavalry, and infantry sent from the Cape. The entire force numbered 3,759 Europeans, and 4,127 Asiatics, making a grand total of 7,886. It continued in Egypt till June, 1802, that is, a period of fifteen months. As already stated it had no fighting to do, so that the casualties which occurred were altogether due to endemic causes, and accidents incidental to ordinary service in that country. These particulars premised, records before us show that among the Europeans there occurred during the time in question 315 deaths; that there were sent away to India and England as invalids 117; equal to a ratio per 1,000 per annum of 105 under the former head, 37 under the latter, and to a total ratio of loss by both causes combined of 142. Among the Asiatic troops the deaths numbered 377; the invalided 41; equal respectively to 114 and 12, and a total ratio of loss of 126 per 1,000. So far, therefore, the results obtained show, on the occasion referred to, that, whereas the ratio of deaths was greater by 9 per 1,000 among the Asiatics than among the Europeans, that of invaliding was only one-third of what it amounted to in the latter; yet that the

"wear and tear" of the force by disease was so nearly alike in both classes that it amounted only to 16 more in the one than in the other. The balance, small as it was, was against the British.

To quote the words of Sir James McGrigor, from whose "Sketches" much of the data for the present remarks are gathered: "Perhaps it may be thought that I have descended to a great degree of minuteness. However, I conceive that from the facts stated important and useful deductions may be made. I think it a matter of regret that such journals are not more frequently kept; with a little industry on the part of the profession they might always be so. Had such records been always faithfully kept, many practical points would not, as they now are, be involved in doubt and uncertainty." (Page 56). The words quoted were printed in 1804.

With reference to the diseases by which mortality occurred, the statistics available show that their ratio of incidence differed to a great extent in the two classes of troops already alluded to. Taking the diseases as enumerated in the "Sketches" (Table II.), the subjoined abstract represents actual numbers of deaths by each respectively among Europeans and Asiatics, namely:—

Plague ...	38	Europeans ...	127	Asiatics.
Fever ...	18	" ...	92	"
Liver ...	64	" ...	12	"
Dysentery ...	148	" ...	47	"
Diseases of the lungs... }	4	" ...	6	"
Stroke of the sun	2	" ...	—	"
Casualties and diseases unknown }	41	" ...	93	"
Totals ...	315	" ...	377	"

In the above abstract the "diseases unknown" include casualties the precise nature of which is unrecorded, small-pox and other cases lost in the *Julia* hospital ship; also nine deaths which happened in corps previously to the surgeons taking charge of them.

Before passing on to consider the remarks made eighty years ago upon the diseases incidental at that time (shall we say only then?) to troops employed in Egypt, a few notices from the "Sketches" may serve to indicate certain points bearing upon hygiene of armies in the field that seem to have an importance of their own if considered in reference to our forces now operating there.

Although a good deal of sickness had occurred among the troops during their long voyage to Suez (this is now avoided by our modern means of transport), the general state of health was so satisfactory that "rarely indeed have troops on any expedition been landed" in equally good physical condition (p. 58). When sickness attacked the troops it affected in different degrees those of the same class who came from different localities. Thus, of the artillery, the Bombay suffered the most; next to them the Royal; next the Madras; then the Bengal; and least of all the horse artillery. The prevailing diseases were dysentery and hepatitis. At one time fever prevailed among those from Bombay. The cavalry continued remarkably healthy throughout the whole period of occupation. Some of the infantry, having performed a long and arduous march across the greater desert, suffered considerably from fever, the disease terminating in hepatitis or dysentery.

Special reference is made to the 61st Regiment, on account of it having been chiefly composed of young men. When that corps arrived in Egypt it was in a high state of health and discipline. At Alexandria it was quartered in the Pharos, the locality damp, and surrounded by sea, except on the side of the mound which connects it with that city. The men became attacked with dysentery and hepatitis, and,

next to the regiment already alluded to (10th Foot) as having suffered from an especially arduous march in the desert, the 61st had the greatest proportionate loss of any in the force (p. 61 and Table II). (How very important therefore in reference to the present expedition are the particulars thus extracted!)

The 80th Regiment had come from Trincomalee. It had been quartered at that unhealthy station during five years, and had there lost many men. On landing in Egypt the regiment was very healthy (p. 61). It was composed of drafts of men from other corps who had volunteered to it after having themselves served in India "fifteen or twenty years." At Ghizeh, El Hammed, and Alexandria they were the most healthy corps. Many of the old men suffered severely from the march to Alexandria, and especially during the cold weather; yet many others who were never free from liver complaint at Trincomalee never complained of it in Egypt. (These are also very important points, in one respect as bearing upon the views entertained now-a-days on the subject of old men, and old soldiers, in another as illustrating the very striking curative influence exerted by "climate" in cases of liver disease.)

(To be continued.)

THE CHINESE MATERIA MEDICA.

By FREDERICK NEWCOME, F.S.S.

(Concluded from page 108.)

Of animal products, musk probably stands highest in repute among Chinese doctors, but owing to prohibitive prices, the use of it is confined exclusively to the wealthier classes. For the pure unadulterated article obtained from the male *moschiferus*, or Thibet musk, from twenty to forty shillings an ounce is the common price to pay, and although the dose given is small—seldom more than half a drachm to a drachm at a time—it is impossible that the poor can afford such a luxury. Even high prices are frequently paid *wholesale* by Chinese merchants for home consumption, and this fact, viewed in connection with the average value of the musk exported to this country (during last year it was less than a guinea an ounce all round), leaves but one conclusion in our minds, namely, that the supply for this market is adulterated to a greater or less extent, despite London druggists charging for it gold price or higher. Last year (1881) the total exportation from China amounted to 1,877 catties, or say 2,503 lbs., valued at 149,780 taels, or about £41,501; in other words, the average was something like a guinea an ounce, whereas true musk always fetches from thirty to sixty shillings an ounce at Shanghai or Tientsin. Here, again, it is just possible that some of the unfavourable results attributed to musk, and its bad repute among Europeans, may have been owing to adulteration, which, as everyone knows, was, and still is, largely carried on.

Bezoar stones are equally in repute, almost fabulous sums being given for the genuine article. For *Bezoar bovine*, classified in the Returns of Trade as "Cow Bezoar," the export price varies from four to five hundred taels the catty; that is to say, from £6 to £7 10s. per ounce. Probably, however, several kinds of bezoar, including stones derived from animals of the goat tribe, are included under the generic term; but upon this point our knowledge is deficient. When such an astounding price is paid for the Chinese article by native dealers, there is little wonder if the samples that formerly reached Europe were spurious as alleged. Whether there is any great medical virtue in bezoar, or whether there is none, is a question that will probably be decided in time; but to settle the point it is necessary to examine and test the true Chinese article, which evidently cannot be sold under double its weight in gold.

The Chinese also import a considerable quantity of Indian Cow Bezoar. This, after transport to China, is

only worth about 8s. to 9s. an ounce, or [barely one-twentieth that of the genuine native article, which we have no hesitation in asserting to be one of the dearest drugs in existence. Beargall is another expensive animal product, being commercially worth some sixteen shillings an ounce in Shanghai; but for what medical purposes it is used we are unable to state. All we know is that it forms a part of their *materia medica*, the same as do the ordinary vegetable nutgalls, with which the country-side everywhere abounds.

Although allusion has already been made to a considerable number of Chinese drugs, the list is still far from perfect. Hundreds more could be enumerated, and yet our task would be incomplete. Indeed, all that can be done within the limits of this series of articles is to particularise the more important—those which play a recognisable part in the commercial economy of the empire.

In their everlasting struggle against disease, these remarkable people have evidently ransacked the whole vegetable kingdom from end to end. Nothing that afforded the least hope of relief seems to have escaped their attention, nor have the other products of Mother Earth wholly passed unnoticed. Several kinds of earth have been made to pay homage at the shrine of *Æsculapins*. One—*hoa-che*—deserves some passing comment. From this stone, or rather from this species of chalk, the Chinese manufacture their finest porcelain vases. At the world-famed factories of King-te-ching, *hoa-che* is commonly used instead of kaolin whenever transparency is the chief desideratum, or expense but a secondary consideration. However, like many things in China, it serves a double purpose, physicians preparing from it a draught said to be aperient, cooling, and detersive. When first dug up, the stone is exceedingly glutinous, bearing a strong resemblance to soap, and from this peculiarity it presumably derives its name of “*hoa*.”

Little progress has yet been made in the way of gaining knowledge of the properties peculiar to the various metals, and the less said about this branch of medical science in China the better. Excepting a few foreign preparations, with which constant intercourse with Europeans is rendering the native populations at the Treaty Ports slowly conversant, quicksilver is the only metal with which their physicians can be said to have any proper acquaintance. From early times this poison has been given by them in severe cases of venereal or scorbutic taint; but, as earlier remarked, the Chinese as a race have conceived a widespread objection to its use, alleging that it creates impotence in the one sex and barrenness in the other. As an ointment, on the other hand, it is still frequently used by native practitioners, who likewise manufacture a mercurial plaster, in the efficacy of which considerable faith is seemingly placed.

Beeswax plays a by no means unimportant rôle in Chinese medicine, forming the base of most ointments and plasters, in the manufacture of which an enormous quantity is annually consumed. So vast, indeed, is the consumption of beeswax for this purpose that one is inclined to join the good Dominie in crying “*Prodigious!*” That the Chinese should elect to use beeswax as the base for their ointments is somewhat curious, seeing how many other equally suitable substances are to be found within the borders of the empire. Among the many strange and wonderful commodities deemed of utility, silver dross may be specially mentioned. Upon the eternal principle of wasting nothing, “*Ah Sing*” converts this rubbish into a miraculous plaster—a sort of universal “*Heal all*.” That this remedy possesses any intrinsic merit cannot for an instant be supposed. If any cures at all are effected by it, they may be set down to faith and imagination—two tonics of amazing potency. The “red pills of unfailing efficacy,” distributed by the Bancham Rembouchi to the deluded pilgrims who yearly flock in thousands to visit the

famous Lama College at Djachi-Loumbo, also belong to the world of superstition. These pills, it was long since ascertained, are good for little else save filling the empty coffers of this sink of iniquity, and keeping a set of idle vagabonds in luxury, while much the same remark may be made about a dozen other remedies used by the medical Lamas in the interior.

The asserted skill of these worthies is generally recognised as a pretence; but then they understand the races with whom they have to deal. So simple are the Tartars, and so exquisite is the faith they place in their spiritual teachers, that any amount of chicanery or nonsense is credited. According to M. Huc and later travellers, it sometimes happens that the medical Lama, not having at hand the specific medicine he requires, contents himself with scribbling its name upon a piece of paper. This, when rolled into the shape of a pill, is given to the confiding patient, who swallows the indigestible bolus in the full satisfaction that his stomach will derive just as much benefit from it as if he had swallowed the drug itself. Time seems scarcely to have weakened this and a score other wretched superstitions; indeed, quackery is little less prevalent in the China of to-day than in the China described so long ago by Nieuhoff and Le Compte: it still pervades their therapeutics to a vast—we may say, to an inconceivable—extent; but, in justice to this people, we must remember that quackery is equally diffused throughout all Oriental science. Even “*Westernism*” is not free from its pernicious taint. European science always has been, and always will be, subject to a certain amount of imposture; this is inevitable: but, nevertheless, many cures once used by charlatans or empirics alone are now included in the British Pharmacopœia, and this memory should render English doctors lenient in condemning as humbug all Chinese medicines. Besides facts—that is to say, excessive fecundity and comparative longevity—have demonstrated the value of some among their manifold drugs. Doubtless, many are worthless; but some must be good, and it remains for Science to eliminate the chaff from the wheat, and to ascertain which are suited to the European temperament and constitution.

Physicians are not likely to pay much attention to the wondrous stories related about cures resulting from the use of “young deer horns,” “crocodiles’ scales,” and “tigers’ bones”—all of which, by a stretch of imagination, may be included in the Oriental Pharmacopœia. These are probably mere travellers’ tales, and, whether founded on fact or superstition, are simply charlatanism in its more brazen forms. Crocodiles’ scales and a hundred other Chinese nostrums may be dismissed without a moment’s consideration, but English science will do well to investigate to the utmost the several herbs most in favour. Common sense is against the presumption that herbs consumed by the hundreds of tons annually, and which have maintained their reputations for centuries, contain none of the many virtues attributed to them. To argue otherwise would be plainly illogical, else why should China be the most populous of all countries? This consideration alone, it might be thought, should dispose of all objections to properly testing these almost unknown drugs, but we fear it will not. For some occult reason, Englishmen have always felt inclined to deride China and things Chinese. Perhaps the feeling is only natural. Their stupendous conceit and strange aversion to progress early rendered them the laughing-stock of European travellers. Our two wars with them proved simple burlesques—mere holiday rambles for our soldiers and sailors—while in many other respects we have, doubtless, found these people contemptible to a degree. But in double-dealing, adulteration, cheating, and similar recondite sciences, Europe has discovered its match in the “child-like and bland Chinese.” Herein he displays talents and intelligence of a no common order, as all who have frequent dealings with him are bound to admit. Is it not likely, then, that he may be equally

well skilled in the other Arts of Peace?—that he does know a good deal about medicine? What are the facts? What are the pro's and con's? Let us reflect for a moment.

China is credited with containing from one-fourth to one-third of the human race. True, its total area is immense; but, like the Russian Empire, the greater part is sterile, and very sparsely inhabited. China proper is not nearly so large as Russia in Europe, but it feeds a population estimated at about five times as great. Acre for acre, it is almost as densely peopled as the United Kingdom, while general provinces—each singly as extensive as England—find sustenance for three persons to its two. Even little Belgium cannot compare, in the matter of population, with such provinces as Chihili, Kiangsu, Anhwei, or Chéhkiang, although their bulk is many times as great. Neither climatic influence nor personal habits, neither religious nor matrimonial customs, fully account for this preternatural fecundity, especially when considered in connection with the many adverse influences ever working in a contrary direction. From time immemorial China has suffered patiently under a long succession of plagues, pestilences, and famines. With sanitary arrangements that simply outrage all European notions of cleanliness and decency; with habits of life dirty and disgusting in the extreme; eternally scourged with cholera, famine, yellow fever, war, oppression, and a dozen other causes, this surprising people has increased and multiplied to an unparalleled extent. Half-starved, constantly afflicted with some or other disease (as with most Oriental nations, they are subject to diseases in their more active and virulent forms), in short, with every incentive to short-livedness, the Chinese, both male and female, attain to a relatively old age. Large families are common, while, notwithstanding the admitted incompetence of native nurses, the ratio of deaths during, or shortly after, parturition is surprisingly small. Hard-worked, badly fed, hovelled—not housed—and downtrodden from birth to death by the Mandarin classes, the lower orders contrive to live to ages that would render them anything but hazardous lives to assure.

Moreover, children are brought into the world in a fashion that has raised the ire of many an English surgeon, and which would inevitably destroy the life of both mother and infant were Europeans treated in a similar brutal manner. Concerning the utter incompetence of native nurses as a body there seems no two opinions. Every European doctor settled in China bears testimony to this fact, and we fail to remember seeing a single copy of the medical reports, issued by the Imperial Maritime Customs of China, wherein several illustrations are not given of their astounding ignorance. Cases of cross or hand presentation generally prove fatal, unless some foreign medical man is in close attendance. Alone by itself, this incompetence must occasion a widespread destruction of human life; but, further, the lower rank of Chinese are still addicted to the crime of infanticide, though, of course, to an extent very inconsiderable with what was once supposed. These, and many other lethal influences we could mention, tend to retard the growth of population. Yet, live as these people may, or act as they may, nothing seems to stay their abnormal fecundity.

Unhappily, we have hitherto obtained no sufficient data whereby to estimate the mean duration of native life in China, but such few vital statistics as have reached this country go to prove an average longevity quite out of keeping with European expectancy, when allowance is made for the destructive influences alluded to above. May we not fairly ascribe some portion, at least, of this result to the medicines prescribed by native practitioners? Supposing English medical science retrogressed to the bigotry, ignorance, and superstition existing in the seventeenth century, would life be nearly as long, or marriages as fruitful as now,

seeing under what different conditions we dwell? Congregated by hundreds of thousands in our great cities; what would the death-rate probably be had our sanitary arrangements and medical skill remained in *status quo*? In a vast emporium like modern London, with breathing room utterly inadequate for its four million inhabitants, plagues would surely have been about as common as eclipses had not science fortunately made such miraculous advances. Nor would our provincial capitals have found themselves much better off than the metropolis in this respect; and yet, in this connection, we should bear in mind two facts: first, that China is, in most respects, two centuries behind Europe; and secondly, that several of its cities contain a million or more inhabitants, while those holding between one hundred thousand and a million are reckoned by the score. Sanitation, or its Chinese equivalent, is a word unknown in a practical sense, the arrangements for removing refuse being simply an offence to English civilisation. Yet, despite this drawback and a multitude of others, the death-rate in Canton, Tientsin, Ningpo, Foochow, and other great centres in closer contact with the west, is comparatively light. What is the reasonable construction to put upon this undeniable fact? Is it not that some real virtue is to be found in most of the local medicines, of which, in the course of a lifetime, the natives swallow such a surprising quantity? The absence of oxygen in a common Chinese lodging-house alone seems sufficient to extinguish the flickering spark of life, while the mode of sleeping is enough to breed a dozen new pestilences. No European, however strong his stomach, could exist a twelvemonth, or even a week, under the distressing conditions which are the common lot of poor "Ah Sing." He would simply asphyxiate and die; yet somehow the natives seem to exist. To call their existence life would be somewhat hyperbolic, seeing they are constantly ailing; nevertheless, the drugs perpetually swallowed counteract, to a large extent, the evil effects of their many objectionable habits.

In concluding this series of papers, it may be in place to refer to a few matters that have hitherto been overlooked, or else have met with scant notice. We have already mentioned China root as among their favourite drugs. Of this plant (the *Smilax China*) such enormous quantities are consumed that it invariably obtains separate notice in the Trade Returns. It is put to much the same purposes that sarsaparilla is with us, and apparently answers as well, though experience certainly goes to show that the *smilax sarsaparilla* of Jamaica is the superior herb where European ailments are concerned. Fuling medicine is also largely used by the Cantonese; but here, again, we must admit to partial ignorance of its character and uses.

In the matter of oils the Celestials are exceptionally great. From sandal wood, cinnamon, red pepper, juniper seeds, aniseed, cassia, and cassia leaves, and many other spices, they express essential oils employed medicinally among other purposes. Even the oils extracted from tea and flower seeds are made to serve some curative purpose or another. In brief, scarce one vegetable or animal substance exists that has not, in the course of ages, been devoted to the service of *Æsculapius*—that does not minister to the necessities of China's millions.

For some occult reason—fortunately, or unfortunately, shall we say?—science has hitherto paid little attention to this interesting study. Few investigations have been made into the qualities of the thousand and one drugs that kill or cure one-quarter of the human family; and those few, we fear, were more the outcome of a desire to expose than of anything else: certainly they were not inspired always by the highest of motives, nor from a desire to add fresh items to the already over-lengthy list in the British *Materia Medica*. The long and short of the matter is that the nineteenth century, which prides itself upon its enlightenment and knowledge, remains in comparative ignorance regarding

the whole subject of Chinese therapeutics. This vast, this most fertile, field for research is as yet but partially explored. Perhaps one drug in ten finds a place in our wholesale druggists' lists; scarcely more, even if we include the several animal products with which the eastern and western worlds are equally familiar. Is this because the medicines themselves are worthless, or because they have been insufficiently tested, if tested at all? The writer's opinion leans to the latter hypothesis.

Clinical Records.

INTRA-ABDOMINAL FIBROUS TUMOUR— CÆSAREAN OPERATION—RECOVERY.

Under the care of DR. CATALIOTTI.

In October, 1879, the maid servant of the Princess Giardinelli came under notice as having a large intra-abdominal tumour which was causing her great pain. She was on the eve of marriage when Dr. Cataliotti examined her, and he was chiefly consulted as to whether she could enter into wedlock without endangering life.

Her antecedents proved that in youth she had always been healthy, with regular menstruations. She had been at a convent where, at the end of the twelfth year of her stay, she lifted a heavy kettle, when she felt a pain in the abdomen. About a month later, at the time of menstruation, she spat blood and had violent hysterical attacks. Having left the convent, she accepted a situation as maid to the Princess, where she was seized with repeated vomiting during menstruation; it was not checked by any remedy, but stopped suddenly after the two first days. At the same time a tumefaction appeared on the lower part of abdomen, of which the origin was uncertain.

This much being known, the abdomen was examined, although certain indispensable observations could not be made, patient being a virgin. The tumour occupied chiefly the middle of the abdomen, extending beyond the umbilicus, had its chief dimension towards the right with a large lobuliform extension towards the hepatic region, and descended deeply into the cavity of the left iliac region. This tumour, most irregular in shape, hard in some places, soft in others, was but slightly movable and sensitive when touched. The patient being in the knee-breast position, the tumour was found adherent in its dorsal parts. The general state of health had suffered materially through continued illness, and the consequent abstention from nourishment. The diagnosis arrived at was that it was a case of an inter-peritoneal fibrous tumour, most likely uterine.

In spite of the representations and warnings of the medical attendant the patient was married on the 9th February, 1880, being already in her fortieth year. After one catamenia she became pregnant. The pain was not long in reappearing, and after three months became intolerable. Called in to alleviate it, Dr. Cataliotti was unable to assist her, and the pains increased to such an extent that in the fifth month the poor woman was unable to sit or lie, and only found some relief in constant walking. Overcome by fatigue, she rested against the wall or in the corners of the room. She complained of continual shooting pains in the abdomen, and this lasted until the operation, when she repeated despairingly, "Cut me to pieces."

In the seventh month Dr. Cataliotti was again requested to procure premature confinement. The condition in which the vagina was at that time rendered this difficult. Introducing his finger into the vulva he found at the right a large tumour, immovable, and of excessive hardness, apparently emanating from the corresponding ischium. The tumour gave the vagina a conical shape; the neck of the uterus was curved on itself, and seemed to have no share in gestation. Then, as far as possible, he tried to introduce the point of his forefinger in order to reach the head of the fœtus, but the patient moved so much that this was not possible. At any rate, the vagina was so contracted as to render the passage of the head of the fœtus impossible, and likewise preventing the introduction of any instruments or the hand. After consultation it was agreed to attempt Cæsarean section. Two days later contractions of the uterus set in, with unbearable pain, especially in

the epigastrium, the thorax, and more especially in the shoulders. On the 28th October, the patient having been suffering for hours, Dr. Cataliotti, assisted by several other medical men, then proceeded to perform the operation. At half-past one the patient was placed on the table. She was resigned and seemed even impatient at the delay. Chloroform being administered, an incision of about five inches in the linea alba between the umbilicus and the pubes was made. When opened, a jet of serum escaped, indicating dropsy, which in itself compromised the success of the operation. This exceptional fact will be interesting from a pathological as also from a therapeutic point of view. The operation was interrupted by the abundant flow of the peritoneal effusion, and the uterus offered exceptional resistance, being entirely covered with varicose vessels. The amniotic fluid was of a limpid colour, and the fœtus extracted in good condition. The umbilical cord was cut and the placenta taken out without any adhesion. This done, everything was cleared and put into order. The carbolic acid spray continued, and as the patient showed signs of coming to, the chloroform was again administered.

The operator then introduced his hand into the abdomen in order to ascertain the position of the tumour and its adhesion. The tumour formed an integral part of the uterus, its walls had entirely disappeared, and had been replaced by the neoplasm. Near the incision a mass of substance was found reaching the hepatic region. The assisting medical men having confirmed these observations, the mass was easily removed, excepting near the liver, where it was hardened by the pressure, and more adherent. Having freed it, the operator enlarged the primary incision in the direction of the umbilicus three inches to the left. He then lifted out the tumour with the whole of the uterus and adhesions. This part of the operation was extremely successful. The remaining part of the neck of the uterus being drawn out as far as possible, was next tied with a strong piece of wire fixed with a knot. Another ligature was also made half an inch lower with a piece of catgut in order to secure the former. The operator had to carefully avoid coming into contact with the bladder or the rectum, which were now in direct contact with the remaining part of the neck of the uterus; a small sharpened metallic sound between the two ligatures fixed the uterine parts outside the abdominal wall.

The operation had lasted about an hour in all. The patient was then removed to a room where a warm moist temperature had been established, and a few spoonfuls of curacao were administered to her.

During the first three days subsequently there were several slight attacks of retching accompanied by heartburn and tympanites. The patient complained of a dull pain in the abdomen, the temperature rose to a maximum of 33° C. and the tongue was dry. These symptoms indicated intestinal disturbance, more mechanical than vital; but applications of ice, lukewarm injections and hypodermic injections of morphia, and a few drops of tinct. opii. afforded relief.

After two consecutive evacuations the patient had good nights till the third day. On the fourth day the bandages were removed, when the wound was found to be nearly healed, except where the pedicle emerged and where the wound was still open, the pedicle being mortified by the strangulation through the ligature. The open wound was in good condition, and reparation continued with wonderful rapidity. The fifth day the urine flowed spontaneously without the aid of a catheter. The abdomen had gone down, and the patient felt sufficiently well to ask insistently for more solid food, and was given a little broth. On the seventh day the piece of wire fell off, and only the catgut remained. On the side of the pedicle there was putrid matter in rather large quantity of a greenish colour, which required two applications a day. The rapid gain of strength alleviated the fears of purulent dropsy. On several occasions opium and bismuth were given to stop excessive evacuations. The pedicle having fallen off the discharge of pus diminished. The patient slept quietly, and the temperature relaxed to 38° C. The moral condition was excellent, the appetite considerable; the wound granulated visibly, but did not yet make any rapid progress towards cure. The suture was still maintained for several days, and there was no great resistance in the tissues. The general condition had evidently suffered severely, as well from the pain caused by the operation as by the diet which had necessarily to be observed during the last two months of pregnancy. On the fifteenth day the suture was entirely removed, but another stitch at the lower

part of the wound was necessitated on account of the diseased state of the edges. On the eighteenth day, the weather having suddenly changed, the patient had an attack of rheumatic pleurodynia, which defied all medical remedies. The new stitch in the wound gave way in consequence of the tenderness of the tissues, and the wound had, therefore, to be treated by canterisation. To keep the borders of the wound together a dry suture was made with collodion, which, however, was not successful. The iliac prominences rendered the use of diachylon impossible. Bands of court plaster were, therefore, placed on the wound, and fixed with small pieces of thread over the thighs, and fixed with ordinary gum, which proved most successful. So far the patient had been progressing favourably, and could have even risen had not the state of the tissues prevented. She ate and slept well, when suddenly a dry colic set in, accompanied by retching of a bilious green substance. Violent pains in the region of the spine with absolute constipation, such as even to prevent the emanation of gases, depressed pulse, dry tongue, intermittent sobbing, and depressed looks were the symptoms which caused fears of a fatal issue. All the most radical remedies were at once applied to avert the danger. Drs. Poggi and Urso again assisted Dr. Cataliotti, and they succeeded in relieving the patient. Irritant injections produced copious foetid discharges, which proved the intestinal obstruction was caused by the reduced peristaltic movement during so long a period through pressure of the tumour. The slow digestion and the heavy food to which the patient was unaccustomed probably caused these symptoms. An error of diet must have been committed, and therefore two confidential nurses were put to watch her until she was quite restored.

Her voracious appetite was such as to necessitate constant restraint, but, on the other hand, the nourishment she took rapidly restored her strength. The dry suture sustaining the wound, the same healed very slowly. It was constantly necessary to touch it with nitrate of silver. The funnel-shaped aperture gradually became smooth, and the scar was completed towards the end of the third month. Lastly, to protect the walls of the abdomen against any strain which might occur, and to guard against any accident which might arise in case the wound were not perfectly healed, the patient was bandaged with flannel.

Dr. Cataliotti expresses an opinion that this case, with its complications, presents some entirely new features, and he lays special stress on the occurrence of acid dropsy which was specially noticeable by the undulating movements of the abdomen, which was filled with the water from the amnion. The diagnosis of this was most difficult. It was confirmed by the motion of the fetus and by the fluctuation of the liquid which was concentrated, and the abdomen did not present the form usual in cases of common dropsy, because it had been completely deformed by the pregnancy, which one might almost say was within the tumour. It was not possible at the first examination to fix the exact position of the uterus, because the left lobe of the tumour descending into the lower part of the iliac cavity had displaced the corresponding wall of the vagina, rendering the neck of the uterus tortuous and not attainable by surgical means. A long and deep furrow divided the tumour of the uterus, and all the medical men were agreed that this organ had been displaced by the settling and slow development of the neoplasm, which was exceptionally hard. The uterus could not be easily distinguished before the operation, because, during pregnancy, the fetus formed the chief part of the tumour, and the furrow divided the tumour and fetus, the large lobe adhering to the concave part of the liver. The fetus, the tumour, and the uterus forming but one rendered accurate diagnosis impossible. Pathological anatomists say that when the uterus contains a new growth the complete development of the fetus becomes impossible. Dr. Cataliotti quotes two other cases of some interest; in one case a living child was born, although a tumour existed in the womb.

The patient above referred to returned to work as maid to the Princess Giardinelli, and was evidently entirely restored. A subsequent examination per vaginam showed that the organs had resumed their normal positions.

Medico-Military Items.

A CABINET MINISTER'S LEISURE.

THERE are few things more indefinite than a Cabinet Minister's leisure, and the reply to the appeal of a body of public servants that the subject of their remonstrance shall receive attention when that particular period has arrived is equivalent to classing its fulfilment in point of time with the lying down of the lion with the lamb. A year and a-half ago, when the sad list of killed, wounded, and sick among the medical officers who had served in the Cape, the Zulu, the Afghan, and the Boer wars had reached a serious total, it was brought by Mr. Findlater to the notice of Mr. Childers, in the House of Commons, that the Army Medical Department, notwithstanding their full participation in all the risks of war, were, by the introduction of the word "combatant" into certain recent warrants, excluded from the benefits conferred upon all other commissioned ranks of the army whose duties led them to be present upon the field of battle. To this the Secretary of State replied with more sophistry than justice, "I cannot undertake to lay down the broad proposition that *non-combatant* officers are to have all the advantages of combatant officers, unless the converse be also accepted; but when I have more leisure I will look into it." During the lapse of eighteen months that expected leisure has not arrived.

In the concluding action of our last war on the fatal Majuba Hill, out of five officers killed, two were medical officers.

In the opening fight of the present Egyptian campaign at Kassassin Loch the only officer killed was a surgeon-major. Surely it cannot need much leisure to enable Mr. Childers to arrive at the conclusion that medical officers, though not receiving the advantages of combatant officers, share to the full their disadvantages, and it will scarcely require much time on the part of an unbiassed observer to perceive that nothing but the rooted jealousy of "those boulders of prejudice and superstition" compels medical officers to continue to be killed on the field of battle as *non-combatants*.

CERTAIN ITEMS OF EQUIPMENT OF OUR TROOPS IN EGYPT.

ACCORDING to a published list of equipment and supplies issued for the use of the army now engaged in Egypt, every requirement, both in a sanitary and medical point of view, appears to have been provided for on a most liberal, if not actually lavish scale. For the protection of the troops when encamped, double tents have been issued to them in the proportion of one to ten men, in place of the ordinary single tents. The helmets of the men are covered with brown cloth. Not only are their eyes protected by "goggles," but the eyes of the cavalry horses are so also, by "fringes." Each man has a blanket of grey warm material. Camp kettles, for cooking, are supplied in the proportion of one to every five men. Each battalion has accompanying it two water carts. Pocket filters are issued in the proportion of fifteen to every hundred men. Arrangements on an elaborate scale are also made to ensure as far as practicable a supply of drinkable water. Each man has on his person a small quantity of bandages, calico and lint. No mention, however, occurs of a card of identity, and the experience subsequent to the skirmish at Kassassin shows how desirable such a means of recognising some of those who had fallen would have been on that occasion.

Dr. JOHN MACMUNN, has left a sum of £200 to the Royal Medical Benevolent Fund Society of Ireland, and £1,000 divided among several Irish medical charities.

"SANITARY" INSTRUCTIONS FOR OUR TROOPS IN EGYPT.

It was to be expected that the authorities at the War Office would issue a code of instructions with a view to protect the health of the British troops now serving in Egypt. Considering the great advances in the science of sanitation said to have taken place of late years, and also the very elaborate details with which that "science" has come to be surrounded, if not *mystified*, the terms of the "instructions" in question have been looked for with some degree of anxiety.

The code in question includes the following instructions—viz., not to encamp upon ground recently flooded, nor upon ground recently occupied; camps to face the North; the vicinity of burial places to be avoided; to avoid drinking turbid water—it should be allowed to subside, or a little alum added to it, or filtered or boiled, or have tea infused in it. In the event of cholera or "typhoid" fever prevailing, the water to be boiled. As to meat, that containing parasites should be rejected; all should be inspected; cooking to be thorough. The use of fruit and vegetables to be encouraged. Tea, coffee, gruel, and lime-juice are recommended; the use of stimulants discouraged. The men to have a cup of coffee in the early morning. After exertion they are to allow themselves to cool before they undress. That "a sanitary committee" be appointed, and so on.

With every desire to write deferentially regarding this code, is it not really the case that among the instructions now abstracted from it there are several that no man of ordinary sense would ever think of contravening, even had they never been written? There are others that cannot be utilised under the exigencies of active service against an enemy, and there are some that would be of no earthly use were they put in force to-morrow. Is it not the case that in drawing up codes sanitary, or as regards other matters for the guidance of the British soldier, the terms of such codes have reference to what, according to the estimate of their writer, the British soldier ought to be, rather than to what he is?

RATIONS FOR THE TROOPS IN EGYPT.

It appears that the scale adopted for the supplies of our troops in Egypt is that of a strength of 25,000 men for two months. There is a contract for meat, of which a considerable quantity has already arrived at Ismailia. Preserved meat sufficient for 25 days' consumption, and biscuit sufficient for 30 days have also been received at the same place. Besides large quantities of *erbswurst*, the stores are well supplied with lime-juice and preserved vegetables. Spirits, wines, and tobacco also figure largely. And then there are "groceries," "comforts," disinfectants, and so on, almost in any quantity.

THE EMPLOYMENT OF RETIRED DEPARTMENTAL OFFICERS.

AMONG the Army circulars for the current month one gives power to the Secretary of State for War to employ retired departmental officers under such conditions as he may from time to time determine. When employed, such officers are to receive a consolidated salary, which, however, is not to exceed the amount of their retired pay by more than £150 a year. No retired officer shall, however, be liable for employment after attaining the age of 65. On attaining that age, and on ceasing to hold such appointment, they shall revert to the retired list, with the rate of retired pay of which they

were in receipt when so appointed. Retired officers, while holding such appointments, shall cease to draw their retired pay, and shall receive a consolidated salary, to be determined by our Secretary of State, but which shall not in any case exceed the amount of retired pay by more than £150 a year, and shall include all allowances, except forage, when specially authorised.

Whether the terms declared in the above Warrant are, or are not, sufficient to induce retired officers to resume the cares and responsibilities of active duty remains to be seen. The omission in the published statement of all mention of "house rent" and "servants' allowance" appears ominous. But perhaps the omission is accidental. At any rate, as in the great majority of cases retired officers have taken leases of houses, they will no doubt "consider" the terms above held out to them.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular

Is published every Wednesday morning. Price 6d. Post free, 5d.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

IF PAID IN ADVANCE 1 1 0

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 54 dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 13, 1882.

LAST WEEK'S PROSECUTIONS.

DURING the past week no less than three inquiries have been held into the circumstances surrounding deaths which had been certified in a way to demand investigation. Two of these cases will form subject for further proceedings, but in the third penalties of £10 each were inflicted on a registered medical practitioner and his unqualified assistant. The offence committed consisted in the signing of a death certificate by one defendant, W. H. Dry, M.R.C.S., whereas he had not seen the patient named in it; and in issuing this same certificate by the second defendant, an assistant named Upfield. The

summonses were taken out at the instigation of the Medical Alliance Association, under the Registration of Births and Deaths Act, 1874, and charged Upfield with having given the father of a child he had attended, in the capacity of a medical man, a certificate stating that the child had died of scarlatina, the signature to the certificate being "W. H. Dry, M.R.C.S., L.S.A.," whereas Upfield had been the sole attendant on the child up to the time it died. The result of the hearing was that named above, each defendant being fined in the full penalty.

This case possesses very great importance, and we are glad to be able to congratulate the magistrate, Mr. Bushby, on so clearly perceiving the practical necessity of dealing severely with such offenders. It probably did not assist the latter much to urge against a conviction that the Medical Alliance was actuated by spite, because Mr. Dry was not a member of the Alliance. The contention was, on the face of it, eminently feeble; for we assume that Mr. Dry, being an employer of unqualified assistants, could not, even had he desired to do so, have joined the Association as a member. We confess to knowing little of the Alliance, except to admire it for its prompt and commendable action in several instances; but if it is so constituted that its ranks can by any chance remain open to persons who outrage the profession of medicine by employing unqualified men to impose on the credulous and unsuspecting poor, then it is certainly high time the Society should be remodelled. For the present, however, we shall continue to regard the assertions made by Mr. Dry and his assistant as of an impossible kind.

This case brings out also very clearly a point we have so often insisted on, that the poor who flock to dispensaries are gulled into the belief that they are receiving duly qualified services; and paying sixpence or a shilling a week, as it may be, for advice given by registered medical men. How grossly they are imposed upon such examples prove; and it is with much satisfaction that we note the increasing frequency with which exposures of the fraud are being made. Of the intention to deceive, moreover, it is no longer possible to have a doubt; for when death occurs, as it frequently must, the *modus operandi* of providing the necessary certificate is a clear indication of the deliberate swindling which goes on in dispensaries of the kind Mr. Dry has been conducting. It is no excuse for the employer of unqualified labour to urge that his assistant has been his pupil. He must know that each time he signs a death certificate in a case of which that assistant has had charge, he is committing an act of perjury, inasmuch as he distinctly puts his name to the declaration—"I attended," &c., &c. But he also knows that an unqualified man cannot legally act as a surgeon in any capacity, else why should anyone incur the cost and trouble of qualification? So that it is an act of conscious fraud for a duly qualified practitioner to send one who is not ex-qualified on the errand to which he has himself been called in his capacity as a qualified medical man.

This point is one on which we must again and again insist, for it is one which most affects the cases that are occurring now with such frequency as to be both

alarming and encouraging—alarming, as showing the extent to which evil obtains; encouraging, as showing the exertions made to oppose it. It is raised, too in connection with the second of the three cases referred to above: likewise a dispensary scandal. This inquiry was held into the circumstances attending the death of a coal porter, who was attended for some time preceding death by an unqualified assistant named Power, who had charge of two dispensaries in Islington, and who "had walked some of the hospitals in America." On the death of the coal porter, who was seen when in a dying condition by a qualified practitioner, the latter arrived at a very different diagnosis of the disease from that given by Power, whose verdict was, alcoholism. holiam. Post-mortem examination revealed extensive pneumonia; and these facts being made known to the jury, they speedily returned a verdict of manslaughter against Power. The coroner, Dr. Danford Thomas, in addressing the jurymen on the conclusion of the evidence, expressed a fear that very many London dispensaries are superintended by unqualified men; and we are of the same opinion. He likewise remarked on the injustice done to the poor, who are robbed of fees under the pretence that they are being paid for valuable medical attendance; and though, of course, he did not comment in such terms at the time on this case, we assume that Dr. Thomas would agree that no more typical illustration than that afforded by this particular instance has recently been given of the way in which money is obtained by dispensary speculators from the unfortunate dupes on whose credulity they trade.

The third case last week was investigated at the Westminster Police Court, where a certified midwife was remanded on a charge of being suspected of causing the death of a woman, by administering to her a poisonous drug for purposes of abortion. The prisoner is under remand, and will be again brought up to-day (Wednesday) in connection with the charge, which, however, is somewhat different in nature from the others we have dealt with. It has, also, less direct importance for the profession; and if substantiated, it will only serve as an indication of the fact, scarcely doubted by anyone probably, that the precautions taken to ensure that none but worthy candidates for midwifery certificates shall receive them, are not proof against the admission of an occasional black sheep. We may regret the circumstance, but cannot easily, at present, avoid its possible repetition.

CERTAIN PHASES OF THE OPIUM QUESTION.

As a matter of public health, the opium question must always possess an interest, and in these remarks our references are drawn from official and other documents of very matter-of-fact nature, in relation to the use of this drug in different parts of the globe. It appears for example that in 1871 there were in the city of Kiu Kiang on the Po-Yang lake, 197 opium smokers. Of these some had smoked the drug almost thirty years, others during various periods down to ten years, but apparently none for less than that period; hence it was probably only those who had persisted during a decade in the habit who

were looked upon as experienced smokers. It is especially observed, however, that the whole of these one hundred and ninety-seven persons had, during the year named, applied for medicine to break them of the habit. And yet it would appear that the use of opium has its advantages. Thus, not only has it the reputation of operating as a prophylactic against malarial fevers, but that several persons who had abandoned the practice became attacked by ague with or without diarrhoea; also that two opium smokers having been similarly attacked, the circumstance was looked upon as altogether exceptional. At Peking, in the same year, opium was described as being "of all our luxuries, the surest destroyer of health, prosperity, position, and life." In the reports for 1877-78 we learn that in Wenchou poisoning by opium is common during certain seasons of the year; also that during the prevalence of cholera, opium smokers, when attacked, almost always succumbed to the disease. It is observed also that the effects of opium, when consumed in smoking, differ from those of the same drug when eaten, or when injected hypodermically.

According to official reports, the use of opium is very frequent among the native criminal classes in Burmah. Of the native prisoners in jail at Rangoon in 1881, twenty three per cent. were addicted to opium smoking. Of this number, twenty per cent. had suffered in health or constitution from the practice. It is observed, however, that the sudden deprivation of the drug to which they were subjected in prison produced no ill effect upon them—a circumstance which is somewhat opposed to the usually entertained belief as to the difficulties and dangers which attend sudden cessation of the habit. Thus, the results of most recent observations fully confirm the statements made by a late Commissioner of that province with regard to the demoralisation, misery, and ruin produced among the Burmese by opium smoking. In fact, there is reason to believe that evil results from the use of opium are even more pronounced among them than in China itself. The great and rapid increase of opium smoking among the criminal classes in Burmah has become a subject of serious importance. Its extent is shown by the fact above recorded, that whereas in 1880 thirteen per cent. of the prisoners in Rangoon jail were opium smokers, the proportion in 1881 had increased to twenty-three per cent.

A second report of the Customs Department in China gives some very interesting particulars regarding the use of opium in that Empire. From calculations therein detailed, it appears that opium smokers in proportion to the population number about three and a third per thousand; that the average smoker expends daily in the purchase of opium a sum equivalent to tenpence three farthings sterling, provided he indulges in the foreign drug, but only equal to fivepence farthing if he is contented with that grown in the country itself. As to the total amount in money spent by China upon this luxury, including that produced at home and imported from abroad, it is estimated to be no less than twenty-five millions of pounds sterling per annum. Chinese who have studied the question are opposed to a traffic which more or less harms smokers now numbering over two millions, and annually

increasing. At the same time, they admit that opium provides a large revenue; that the expenditure for opium, and liability to the incidence of opium taxation, touch an infinitesimally small percentage of the population; and that neither the finances of the State, nor the wealth of its people, nor the growth of its population can be specially damaged by a luxury which only draws from fivepence to elevenpence a-piece a day from the pockets of those who indulge in it—namely, two-thirds of one per cent. of the population. They admit all this, but they do not find in either the revenue produced, or the statistical demonstration of its percentage innocuousness, any sufficient reason for welcoming the growth of the trade, or for desisting from the attempt to check the consumption of opium. In reference to these remarks, however, it is asserted that in 1854 the estimated number of persons in China addicted to opium smoking was three millions; that in 1871 there were supposed to be three or four millions of smokers; and that more recently the numbers have increased to six millions of smokers; moreover, that "there is a deeply-rooted conviction in the Chinese mind that opium does unutterable harm to the country." In America the habit of opium smoking, introduced in 1863, has already spread to an alarming extent, not only among Chinese, but also among Europeans.

The first mention of the use of opium by the Chinese occurs in their Herbal, (a) written over two hundred years ago. Under the name of *opien*, the drug was then manufactured from the native grown poppy; but there appears also to have existed a foreign trade with the drug, the Portuguese alone importing it, and continuing to import it up to the year 1767. With the fall of the Mogul Empire, the monopoly of the growth of opium in British India descended on the conquerors. In 1773 the English made their first venture to introduce it to the China market. In 1796-9 the Chinese Government prohibited its importation, and forbade its consumption, under severe penalties, but without lessening in any way the quantity entering the country, as smuggling and bribery from that time forward took the place of open trade. In 1839 the seizure by the Chinese authorities of the opium on board British ships led to the "opium war," which continued during the subsequent three years. From the date of its conclusion till 1858, smuggling continued as before; but in that year, in accordance with Treaty, opium was admitted at certain ports, subject to a duty. In 1860, after a second war, the Chinese legalised the trade—whether under compulsion, or of their own good will, is a question apparently answered variously, according to individual predilection. In 1869 an appeal against the traffic was made to the English Government, who, it is asserted, "passed it by unnoticed;" and so, "from the beginning of this century to the present hour, opium has been cultivated in India expressly for the China market." Then follows a series of tables, for the purpose of showing the steady increase from this source to the revenue of India, from £838,450 in 1834-5 to £6,521,456 in 1877-8, the total net revenue of that Dependency being in the first-named period £14,392,309, and in the second £38,666,484. According to the Budget statement recently made in the

(a) "Opium Smoking," by H. H. Kane, M.D. New York. 1862.

House of Commons, the estimated revenue from opium in India for 1881-2 was £7,250,000.

The opium question, in as far as it bears upon the finances of India, has been discussed somewhat after this manner:—To sever the direct connection of the Government of India with the trade would be—so it is surmised—to stimulate instead of checking the consumption of the drug, not only by the Chinese, but by the natives of India; while to suppress the trade would be to entail bankruptcy on the country for the sake of an illusory advantage. The Chinese, if unable to obtain the drug from India, would procure it from somewhere else, and home production of it would greatly increase. In addition to this, the abolition of the opium traffic would entail upon the Indian Government a loss of five millions sterling per annum, and besides would for a time at least, so depreciate exchange as to derange the commercial relations of the country. As matters stand, the duty on salt in India has been reduced on the strength of the opium surplus in the last Budget. Thus our own subjects have directly benefited. Hopes have also been expressed that the charges on salt may be still further reduced from a continuance of the same surplus, although the uncertainty of the latter is well known and recognised. In reference to the revenue which India derives from the opium trade, the remark has been made that that revenue is as justifiable as the Excise duties of the United Kingdom, and that few administrators would seek altogether to abandon the latter as an item of public revenue; and, further, that sumptuary laws have never succeeded. In reference to the views thus obtained from official utterances, however, the circumstance is noteworthy that according to recent accounts from India the export duty on Malwah opium has been reduced by Rs. 50 per chest to enable that drug to compete with the opium grown in Persia and China. The circumstance has an important significance. It shows that the revenue from this source must be fluctuating and uncertain; that, therefore, upon fiscal grounds alone the cultivation of the poppy must less and less be depended upon; that other industries must more and more take its place.

From these references, therefore, several points are prominently brought out, namely, that confirmed opium smokers, as a very general rule, are themselves very desirous to abandon the evil habit. That the drug (in moderation) is considered to be a prophylactic against malarial fever, although its operation as such is not invariable and constant. The evil effects of opium in regard to health, morals, and prosperity are acknowledged and represented by the Chinese themselves. The effects differ according to the manner in which the drug is used. In Burmah, a large and rapidly increasing proportion of the convicts are addicted to the use of opium. There is reason to think that in China the actual number of persons addicted to opium smoking far exceeds the official estimate, also that the vice is rapidly extending in that empire. Opium smoking only introduced into America so recently as 1868, has there already increased greatly. Although the opium traffic with China existed before it was taken up by the British, it has greatly increased under them, and at the present time supplies a very material item in the revenues of India. Importation of the drug into China prohibited by the Chinese Government was subsequently effected by

illicit means; it led to two successive wars, and according to some accounts is now legalised by the Chinese against their own convictions. The drug is cultivated in British India, especially for the Chinese market. It is argued that to sever the existing communication of the Government of India with that trade would tend to increase the supply and demand for the drug. It would further involve a serious pecuniary loss to the Government, and also derange financial transactions with England; it would moreover necessitate increased taxation on salt in India. Finally, the revenue which India derives from the opium traffic is considered to be as justifiable as is that which England derives from her excise duties.

Therefore, the whole gist of the matter is that the opium traffic is confessed to be most pernicious in its results alike to health and morals of a large proportion of persons in China, Burmah, and America, nevertheless; but as it supplies India with a very large money revenue, on the same principle that excise duties add materially to the revenues of the United Kingdom, the continuance of that traffic on its present footing is unavoidable. But inasmuch as the extent to which opium is now produced elsewhere than in India has already to a material degree affected the revenues from this source in that country, the fluctuations and uncertainties from the same cause promise in the future to increase from year to year.

THE MEDICAL SIDE OF THE WAR.

A SEVERE and trying climate; desert tracts, on the surface sand of which the feet of men and horses sink deeply; scanty and otherwise unwholesome water; food neither overabundant in quantity nor very palatable in quality, such are some of the items that militate against our troops now in Egypt. Of these, the greater number are inseparable from active service anywhere out of the temperate zone; others are in some respects peculiar to that country—among them, notably, the physical conditions just alluded to. With such difficulties, among others to be encountered, it was natural to anticipate the occurrence of a large amount of sickness among our forces; hence it is that the hospital establishments provided for the expedition have been upon a scale as regards *personnel* and *matériel* hitherto unknown, except perhaps those for the comparatively small force some years ago fitted out for Ashantee. With that portion of the force which has proceeded from the west there have been sent not only the means for first help to sick and wounded of individual regiments, but also for field and general hospitals to be established at suitable points; while for such men and officers as, on account of wounds or sickness, require removal from the country, hospital ships are provided for their transport to Cyprus, Gozo, Gibraltar, or England, according to circumstances. As regards the forces sent to Egypt from the east, the liberal and efficient scale upon which the Government of India on all occasions provides for sick and wounded soldiers on active service gives assurance that on the present occasion the principle has not been departed from.

Records of the campaign in which, at the beginning of the present century, our forces were engaged in Egypt, gave ample information regarding the diseases to which

our men on the present occasion are most exposed, as to the classes and description of men most liable to be attacked by them; they further contain ample directions as to the protective measures to be taken against the occurrence of endemic illness and epidemic disease, in the event of the latter occurring. But in many respects our troops are in far better hygienic circumstances than were their predecessors eighty years ago. In respect to food, clothing, protection, and general attention to personal comfort, they are looked after in a manner then not dreamt of. And what is likely to be the result upon their health of such improved conditions? Time alone can furnish a reply. As far as experience on the present occasion has taught a lesson, it is that the diseases most to be dreaded among our troops are fever and exhaustion from exposure to sun and high temperature; dysentery and diarrhoea, partly from the use of bad water, partly from alternations between day and night temperature, and exposure, such as is inseparable from duties in times of war. No doubt it is with reference to the latter diseases that, under sanction of the medical authorities on the spot an allowance of spirits has been issued to the troops; no doubt also, a "tot" of rum under the circumstances is both grateful and beneficial.

So far, our troops are free from epidemic disease in any form. It is true that from the Red Sea on the one hand, and from the direction of Western Persia on the other, danger in this respect is not altogether absent. As regards the first, quarantine imposed for a few days on ships has been removed; as regards the second, no steps whatever have been taken as yet. How far the maintenance of quarantine regulations compatible with military exigencies in time of war is a question not yet presented; neither is it necessary for the time being to consider how far that measure may be expected to prove effectual for its intended purpose. All that need now be said is that, fortunately no measures of quarantine are called for. The general state of health of the army now operating from Ismalia appears to be neither better nor worse than might naturally be expected under the particular circumstances of that portion of the expeditionary force.

According to some of the published reports from Egypt certain difficulties exist in regard to transport, food, and medicines for soldiers in the advanced positions. Such things are inseparable from a state of war, and it is altogether too much to expect or look for regularity in these or any other respect such as characterise the ordinary regimental routine of an English garrison. War cannot be carried on without "roughing," and it is only the physically strong who can, uninjured, go through the process.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bristol 15; Cardiff 16; Derby, Plymouth 18; Norwich, London, Edinburgh 19; Portsmouth Halifax 20; Birkenhead, Nottingham 21; Bradford, Glasgow, Oldham 22; Newcastle-on-Tyne, Leeds 23; Brighton, Leicester, Bolton 24; Huddersfield, Liverpool 25; Salford 26; Dublin, Blackburn, 27; Birmingham, Wolverhampton 28; Sheffield 29; Sunderland, Manchester 30; Preston, Hull 34.

Notes on Current Topics.

Fever-spreading Arrangements.

WE have so often drawn attention to sanitary defects and other causes which contribute to the spread of infectious diseases that it might almost be imagined the number of contrivances of this description has been completely catalogued. Not a week, however, elapses without the belief which encourages such a notion being rudely shaken, and we may confidently anticipate that the ingenuity of sanitary officers will long continue to be exercised in overcoming the constant tendency to invent new means of spreading infection apparent among the more crowded populations of this country. A very striking example to this effect came to light on Friday last at an inquest held at Southwark on the body of a four years' old child, which had died from scarlet fever. The mother of the victim, with an unusually intelligent perception of the relation between cause and effect, attributed the fatal illness of her child to the evil influence of a neighbouring dust-bin, which had some time previously been removed from its original position to a spot immediately beside her own back kitchen. The smells from this undesirable addition to its surroundings rendered the back of the house entirely uninhabitable, and the unfortunate family were driven to live entirely in the front room of the establishment. The children, however, could not be so confined; it was impossible to prevent them from playing more or less closely about the intolerable nuisance near by; and the not surprising consequence was serious illness, terminating so far in the death of one of the children. It was elicited during the inquest that such occurrences may take place with considerable frequency, since the neighbourly feeling which regulates the inter-communication of the poor prevented the registration of such complaints as might have resulted in removal of so great a nuisance. It is quite clear, nevertheless, that under a system of periodical inspection of all tenements and dwellings, existence of a foul source of disease could not long remain undiscovered and unremoved. It may be urged with strict justice that considerable additions would have to be made to our present sanitary service in order to carry out regular and systematic inspections; but it has been so often of late conclusively shown that inspection of this nature can alone be trusted to for effectually remedying a vast number of fatal defects in poorer dwelling places, that it may be well to make early provisions for what will some time else be inevitable. Certainly such frightful dangers as those described before Mr. Collier ought never to be seen in any civilised community.

Sunday Recreation.—How it is Prevented.

IT is now so generally admitted that the efforts of the Sunday Society to secure for the people means of healthy and rational recreation and enjoyment by throwing open public museums, libraries, &c., &c., are calculated to advance the national progress that it is impossible not to feel surprised at the action of a presumably intelligent body of men who condemn the principles involved. Such action, however, has been taken by a society of persons engaged in attending libraries, called the Library Association.

ciation, and which has, during the past week, been holding a series of meetings at Cambridge, under the presidency of the University Librarian.

Among the resolutions proposed was one by Mr. E. B. Nicholson, Bodleian librarian at Oxford, in favour of the general principle of opening museums, libraries, and galleries for at least part of each Sunday. We are informed that in place of discussing it, the previous question was carried "by acclamation." It is right that the circumstances under which this remarkable evidence of sagacity was exhibited, should be remembered. The vote was the vote of men, as a rule, but little cultured, the 'Library Association' being made up almost entirely of the officers who are chosen to superintend free libraries and similar institutions in this country. But few of them would be actuated in a question of the kind under notice by any higher feeling than that of self-interest, which necessarily urges them to persistently oppose any movement, the success of which would entail additional labour on themselves. The few highly cultured members of the Association, like Mr. Nicholson, who is a distinguished Oxford graduate, naturally view the action of their fellow members with deep regret, as also must all who value the welfare of the British Nation. That interested librarians, however, can influence the success of the Sunday movement by passing any number of resolutions of the "we don't want to work" type, is absolutely impossible; but it says little for their intelligence as a body that they should so strongly oppose a proposal for extending the usefulness of their own services.

The Fever at Accrington.

THE epidemic of scarlet fever at Accrington, in spite of all precautions is spreading. One medical man alone reported no less than 20 fresh cases during last week. There were 22 deaths registered, 18 of them being children under eleven.

The Poison of Mushrooms.

A PARAGRAPH has been going the round of the press stating that Prof. Ponfok has been making experiments on the common mushroom, and has discovered that it is highly poisonous, particularly when uncooked. It may relieve the minds of some to learn that the professor's experiments were made on the *Morchella esculenta*, and not on what is generally known as the common mushroom (*Agaricus campestris*). The latter, we have often eaten uncooked, and in pretty large quantities, and are, therefore, quite in a position to place our experiments by the side of the dictum of our contemporary which made the discovery. There is hope, moreover, even for those who have eaten the *Morchella esculenta* uncooked, as the smallest quantity that invariably proved fatal was two per cent. of the body weight of the animal experimented on. This would represent in a person 150 lbs. in weight three pounds of the mushroom in question, a quantity, we need hardly say, not likely to be consumed by one person at one meal.

DR. GRIFFIN reported last week to the Westport Guardians that there were eight cases of typhus fever at present in Clare Island.

An Australian Medical Insurance Fraud.

THE Melbourne *Argus* of May 10th gives the history of a case lately tried in the colony. The principal defendants were Barker and Hicks. Barker who was a trusted servant of the Mutual Provident Society, having acted as a canvassing agent for many years, had a tent in the Exhibition grounds, in which he held forth as to the advantages of life assurance, and solicited business for his company. To him came Hicks, a broker and canvasser for the society, with the suggestion that "this gambling in lives" might be turned to profitable account. His proposition was that some person with only a short time to live should be insured as a "good life" and that arrangements should be made so that when death occurred the proceeds of the policy should go into the pockets of the conspirators. Barker agreed, and it was resolved to effect an insurance for £3,000 in the Mutual Provident Society, and another for £5,000 in the Alliance Assurance Company, making together £8,000. For the purposes of the plot, two confederates were required, viz., a medical man, who would give a false report, and a person to whom the policies might be assigned, for, of course, to make the money directly payable to Barker and Hicks would have been to excite suspicion. The medical man was found in Dr. Horton, while a person named Forsyth, who absconded before the trial, acted as assignee, and the compact was that the proceeds of the conspiracy should be equally divided amongst these four. The next thing was to select a fit subject for insurance, and the conspirators laid their hands upon a man named Weatherhead, who was completely destitute, and almost in the last stage of consumption. He was passed as a "first-class life" by Dr. Horton for the Mutual Provident Society, and another practitioner, Dr. Morrison, was induced, partly by a bribe and partly by a statement as to what Dr. Horton had done, to certify in a similar manner for the Alliance Company. It seems to have been an easy matter to persuade two people who had never seen Weatherhead in their lives to sign their names to the usual "friends" report. The question now was, what to do with Weatherhead, whose end was rapidly approaching. It was not considered prudent to allow him to die in Adelaide, so he was taken to Melbourne, with the intention of placing him on board a ship then about to sail for London. It was merely certain that he would expire during the voyage, and it was thought that he could be quietly buried at sea without awakening suspicion. Weatherhead, however, was too far gone to be taken on board, and he died in Melbourne. At this stage of the affair occurred an incident which requires some explanation. Hicks, (who was accepted as Queen's evidence), swore that the certificate given by Dr. Beaney set out that the cause of death was laryngeal phthisis, and that the deceased had been ill about twelve months. As Weatherhead had been insured for less than six months, this, as Hicks said, "would never do." Upon representations made by Hicks to the undertaker the words "twelve months" were altered to "three months." This was after the certificate had been filed in the Registrar general's office. How such an important alteration could have been made in this manner it is difficult to understand. The conspiracy, therefore, seemed to be in a fair

way to succeed, when the whole fabric of deception was blown to the winds by a simple act of carelessness on the part of Hicks. A tell-tale letter and telegram which Hicks had torn up and thrown on the floor, were picked up by a woman, who joined the pieces together, and read words which induced her to communicate with the Mutual Provident Society. Barker, Hicks, Forsyth, and Dr. Horton were charged with conspiring to defraud the Mutual Provident Society, and Dr. Morrison was charged with defrauding the Alliance. Forsyth absconded, and Hicks turned Queen's evidence. The case was so strong against all the defendants that they would probably have been convicted without the testimony given by Hicks in the witness-box. Indeed, if anything could have saved the prisoners, the fact that Hicks was their accuser would have done so. Barker was sentenced to two years' imprisonment for each offence, Horton to two years' imprisonment, and Morrison (who was recommended to mercy by the jury) to one year's imprisonment.

Neglect of Death Registration.

It seems to us that medical officers of public institutions in Ireland need some more stimulation to discharge their duty in respect of registration of deaths, and that, inasmuch as the official mention of their neglect of duty in the Registrar-General's report does not appear to influence them to punctuality and business habits, it is necessary that that functionary should take, as the lawyers say, "such steps as he may be advised" to enforce regularity in this matter. We are familiar with the paragraphs in the Registrar-General's reports respecting the negligence of certain officials of institutions in Dublin, and we find from the report for this week that the Registrar of Waterford No. 1 District remarks, "*apparent increase of total death-rate due to registration of 14 deaths at District Lunatic Asylum, dating from December 3rd, 1881, to the present.*" It is, we think, a very gross piece of mismanagement in any institution that the deaths therein should be held over for eight months without being reported to the proper authority, and we hope we shall not again be obliged to notice a similar occurrence at the Waterford Asylum or elsewhere.

Alleged Poisoning of a Town by Lead.

THE Keighley (Yorks) Town Council had to answer last week in the Coroner's Court on a charge of having slow-poisoned a citizen by the lead dissolved in the drinking water supplied by them to the town. The widow of the deceased deposed to his death, and that both he and she had suffered two years ago from lead poison. The pathological appearances were suspicious, but inconclusive; but the medical witness admitted that he did not find sufficient disease to cause death except from lead poisoning. Deceased visited him about two years ago, and then he was suffering from lead poisoning. At that time he advised him to discontinue using the water. A juror asked if he had come across many cases of lead poisoning. Witness said he had reported *sixty-four* cases to the local board twelve months ago. The lead was dissolved from the pipes by the action of the water. It was his opinion but for lead poisoning the deceased would have lived an average life.

Newspaper Paragraphing respecting Dublin Surgeons.

WE are reluctantly obliged to notice again the extent to which paragraphing is employed in Dublin as a means to public notoriety. It is not unreasonable that a physician or surgeon leaving his business for a prolonged absence should let his patients know that he has left home in order that they may be saved a fruitless journey to town. But there can be no necessity for the publication of this form of advertisement when a practitioner is going on a commonplace country call for the night, or from Saturday to Monday. Nor is the advertisement at all improved by the statement that the gentleman in question has been summoned by telegraph or by post-card or any of the ordinary means of communication. Two of these announcements have recently appeared—in reference to one Dublin surgeon—in the daily papers of that city, and our opinion has been challenged respecting their style and respecting the following paragraph cut from the newspaper of the locality to which the anxious public had already been informed that the gentleman had gone:—

"Dr. . . . of No. . . . Square, Dublin, Fellow and Examiner (*sic*) of the Royal College of Surgeons, the very eminent and consulting surgeon of Ireland, paid a visit to . . . yesterday, and was much pleased with what he saw of our city, particularly with our noble river, which that excellent authority considered ought to keep us free from epidemic disease. Surgeon . . . returned to Dublin this day."

The ill grammar and errors of fact of this paragraph make it obvious that it was not written by the gentleman in question; but we feel it necessary to say that such a professional puff is indecent, and certainly not calculated to maintain the reputation, honour, and dignity of any person or institution. It needs to be at once publicly and sternly repudiated. Reporters are men of business. They print these paragraphs because they think that their doing so will be agreeable to the person referred to; and they have some justification for that impression when they see every trip for a day out of town "by telegram" chronicled in the fashion columns of the papers. Those who suffer as the surgeon here referred to has done owe it to the profession that they shall at once make the public aware that they utterly repudiate such puffs, and that surgeons of respectability do not descend to such means of achieving publicity.

The Parkes Museum of Hygiene.

THE Council of the Parkes Museum have just acquired new premises in the West-end of London, near Cavendish Square, to which the contents of its present temporary home in University College will be removed as soon as the necessary alterations and additions are completed. The new building will consist of a central hall suitable for meeting and lectures, a library, and corridors, all lighted from the top, and well suited for exhibition purposes. The meetings and lectures on sanitary and other matters connected with the health of the people, which were only occasional while the museum was at University College, will henceforth form a permanent feature of the institution.

Anti-Vaccination.

RECENTLY, at the Leicester Police Court, a large number of persons were summoned for refusing to comply with the Compulsory Vaccination Acts, by not having their children vaccinated. There are several thousand unvaccinated children in the town of Leicester, and their number is increasing at a very rapid rate, although there are more prosecutions under these Acts in this place than in all the other large towns of the kingdom put together. It is urged by the anti-vaccination party that, notwithstanding this state of things, the town is perfectly free from small-pox. This immunity is, however, mainly due to the energetic action taken by the medical officer of health for stamping out the disease upon its first appearance. In the present instances most of the defendants were fined 10s. each, or seven days' imprisonment.

A New Mydriatic.

HYOSCIN, prepared by Ladenburg, and crystallisable by hydriodic acid, has proved to possess, if dropped into the eye, a remarkably rapid mydriatic effect, and surpasses, in this respect, atropia in a high degree. But the solution should be only a half per cent. one, as stronger solutions ($\frac{1}{2}$ per cent.) cause already general symptoms, as, unconsciousness, disturbances of articulation, vertigo, and dryness of the throat. It may be mentioned that this preparation seems to be well tolerated by the conjunctiva, even if kept a long time in contact with it.

The Inland Revenue Report.

THE report of the Commissioners of Inland Revenue for the past year—a report of the Principal of the Laboratory—says that the work under his superintendence has recently very largely increased, the number of samples examined last year having amounted to upwards of 26,000, or an increase of 8,000 as compared with the number mentioned in the last report. This increase is attributed principally to the beer duty and to the new regulations. Besides the analyses made in connection with the Customs, there is now a large amount of work done in the examination of samples of goods supplied under contract. The necessity for the service may be estimated by the fact that, taking the India Office as an example, out of 488 general samples submitted, 87, or 17 per cent., were reported against. Nearly one-half of the samples of wine analysed fell below the standard, and 63 per cent. of the samples of brandy, which by the terms of the contract was required to be derived solely from the fermented juice of the grape, had to be rejected, as containing variable proportions of grain spirit. The adulteration of oils, too, has been found to have lately become very general, sophistication being effected in more subtle and ingenious ways than formerly. For the Board of Trade, 86 samples of lime-juice and 550 samples of lemon-juice had been examined, with the result that 6 per cent. of the lime-juice and 16 per cent. of the lemon-juice (the latter representing more than 14,000 gallons) were rejected. Most of the rejected lemon-juice, though otherwise satisfactory, contained free pulpy matter, having been prepared early in the season, when lemons are required for making candied peel, and the squeezing is done expediti-

ously, so that the juice is looked upon rather as a by-product. The pulpy matter has, however, to be got rid of by filtration before the juice is fit for use on shipboard, and as this operation is tedious, attempts are made to get juice containing pulpy matter passed, in order to avoid the inconvenience and expense of clarification.

British Prudery.

IN reproducing and commenting upon the article by Dr. S. Daniels, of St. Petersburg, on "Diseases of Sexual Organs in the Insane," in our columns under date of August 16, *La France Médicale* makes the following comment:—

"Le rédacteur de *The Medical Press* nous paraît à son tour se laisser avant tout dominer par ses instincts de pudeur britannique. Nous ne pouvons trouver aucune immoralité dans les examens faits dans l'intérêt des malades, et d'autre part nous ignorions qu'on ne pût chez les aliénés traiter toute affection autre que leur folie."

If the editor of *La France Médicale* had taken the trouble to understand what we did say his comment would have been needless. We think it quite consistent with *pudeur britannique* to treat any and all diseases our patients may suffer from; but we cannot say the same of the practice of making vaginal examinations in every case of lunacy occurring in females where there are no symptoms present pointing to possible disease of sexual organs, simply because the patient happens to be insane.

A Man of Great Brain.

ACCORDING to our excellent contemporary *Knowledge*, "The heaviest brain ever weighed in the United States was taken from the skull of James H. Madden, who died at Leadville on July 6th. The doctor who attended him during his last sickness had observed the immense frontal and lateral development of his head, and determined to weigh the brain, but his astonishment was great when it brought down the scales at sixty-two and a quarter ounces. Cuvier's brain weighed sixty-four and a-half ounces, considerably surpassing all other records; but the brains of Napoleon, Agassiz, and Webster, though phenomenally heavy, were much lighter than Madden's. It is an interesting circumstance that Madden was not a naturalist, a soldier, or a statesman, but a gambler."

THE annual death-rate last week in the large towns from the principal zymotic diseases was again below the average, if we except a few towns, such as Hull, Preston, Manchester, &c., where it was excessive, chiefly from diarrhoea, from which disease the mortality ranged last week from 0.6 and 1.0 in Huddersfield and Bristol, to 14.4 and 14.5 in Preston and Hull. The highest annual rates from whooping-cough were 2.4 in Birkenhead, and 2.5 in Blackburn; from scarlet fever, 1.3 in Nottingham and 1.4 in Sheffield and Newcastle-upon-Tyne; from measles, 2.5 in Huddersfield; and from fever, 1.3 in Leeds. The 35 deaths from diphtheria included 18 in London, 9 in Glasgow, and 2 in Birmingham. Small-pox caused 7 deaths in London, and one each in Nottingham, Manchester, Hull, and Newcastle-upon-Tyne.

The Cholera.

ACCORDING to an official despatch from Manila, 233 natives and four Europeans died there in one day last week of cholera, including the American Consul. In eighteen villages in the province of Manila there have been 368 deaths.

FURTHER news of a very terrible nature has been received here from Iceland. The population, who have already suffered severely from famine, is being decimated by an epidemic of measles.

THE University of Wurtzburg, at its third centenary *fête*, made Doctors of Medicine *honoris causâ* of MM. Ranvier and Charcot, and Surgeons of Messrs. Lister and Paget, of London. The Faculty of Philosophy also conferred the same honour on Prof. Huxley and Sir J. Lubbock.

LAST week a patient died under chloroform at the London Hospital in precisely the same way as the one reported in our last at University College Hospital. Both had gone to hospital for the purpose of undergoing an operation for cancer of the tongue, and both died whilst under the influence of the anæsthetic before operation.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 25, Madras 33; Paris 23; Geneva 30; Brussels 25; Amsterdam 18; Rotterdam 23; The Hague 21; Copenhagen 33; Stockholm 37; Christiania 28; St. Petersburg 42; Berlin 30; Hamburg 26; Dresden 26, Breslau 40, Munich 24, Vienna 22, Prague 29, Budapesth, 29, Trieste 31, Rome 22, Naples 31, Turin 22, Venice 34, New York 40, Brooklyn 32, Philadelphia 26, and Baltimore 31.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

A FRENCH SURGEON ON GLASGOW LIMBS.—In an editorial notice in *Le Progrès Médical* of the 26th ult. of Dr. William McEwen's book on Osteotomy, the author is quoted as stating that, having practised 835 osteotomies on 557 limbs, and not having lost a single case as the result of the operation, he does not consider himself as exaggerating unduly in holding antiseptic osteotomy as one of the most certain operations of surgery. It is very reasonably stated by the French writer that it would be difficult to account for this large number of operations, if regard were not had to the special circumstances of the Scotch surgeon; and M. Desmons, of Bordeaux, is quoted as throwing light on the matter in the following terms:—"I considered at the onset how so much rachitis and so much *genu valgum* and *varicous* could be collected in one of the hospitals of a single city. In traversing the city I soon found an explanation of the circumstances. Every moment I encountered persons affected with bow-legs or curvatures of the thigh. It was the more easy to discover these, seeing that numbers of the people, women and children, paraded voluntarily with naked limbs and feet." We cannot help remarking that we regard this description of women and children in

Glasgow as savouring of the mental Orientalism of our Gallic neighbours. It is not at all unlikely that for the women of Glasgow Mons. Desmons may have mistaken some of Her Majesty's gallant forces often located in a suburb of the city.

REQUEST TO THE WESTERN INFIRMARY, GLASGOW.—Mr. A. F. Stoddard, of Broadfield House, Port-Glasgow, has bequeathed the sum of £1,000 to the Western Infirmary, Glasgow, for the upkeep of beds, which sum is to be paid in five annual instalments of £200 each. The amount required for the upkeep of one bed for a year is £50. The bequest will therefore maintain four beds annually for five years. During the past year the Western Infirmary has made considerable progress financially, but as the expense of the Free-laid Wards, which afforded an addition of 200 beds to the accommodation, has fallen upon the institution this year, there is the prospect of a considerable deficit in October next.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 2nd inst., was 89, and the death-rate 18 per 1,000. There were 18 deaths under 1 year, and 21 above 60 years, of which three were above 80 years. Only one death was reported from zymotic disease. It was one of erysipelas, and occurred in the Old Town.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 2nd inst., were at the rate of 23 per 1,000 per annum, against 20 in the preceding week and 21, 23, and 16 in the corresponding periods of 1831, 1880, and 1879.

CUPAR.—DECLINE OF THE FEVER EPIDEMIC.—Dr. Wm. Whitelaw, medical officer of health, forwarded his weekly report regarding scarlet fever to Bailie Simpson on Wednesday last, in which it is stated that there is a great improvement both in the number and the type of the cases. During the last week there have been reported only four fresh cases, all of an extremely mild type. No more cases have proved fatal, and all those which have occurred during the last fortnight have been of a much milder type—an almost unfailing indication that the epidemic is dying out. With reference to the proposal to close the public day-schools, the medical officer states that since they were opened eighteen fresh cases have occurred, and of these only five had attended school. He calculated that of those at school 0.7 per cent. had taken fever, while of those outside 1.2 per cent., or nearly double, had been laid up. The conclusion drawn was irresistible that the children are safer there than roaming about the streets. There therefore seems to be no necessity for closing the schools in the meantime.

Literature.

ON OVARIAN AND UTERINE TUMOURS: THEIR DIAGNOSIS AND TREATMENT. (a)

"The book which I now issue is professedly a second edition of that of 1872, but so far as the operation of ovariectomy is concerned, it is almost new, and as regards the uterine section still more so." Such are the author's words in the preface, and they indicate the vast progress which abdominal surgery has made in the last decade, an advance due in no small degree to the zeal and ability of the author.

Passing over the first 150 pages, which are devoted mainly to the pathology of ovarian tumours and their diagnosis, we come to an interesting chapter on "The Rise and Progress of Ovariectomy," including ovariectomy in France, Belgium, Germany, &c., which is in our opinion an

(a) "On Ovarian and Uterine Tumours: their Diagnosis and Treatment." By T. C. Wells, F.R.C.S., &c., &c. London: Churchill.

Impartial record of the history of ovariectomy, giving due prominence to the services rendered by each of the pioneers of ovariectomy from McDowell downwards.

The author's opinion on the antiseptic system are worthy of serious consideration. After Listerism has been well nigh universally adopted, we have recently seen most violent attacks made on it, so violent as to lead us to fear, in some cases at least, that personal motives have warped the judgment and biased the feelings of speakers and writers. Mr. Wells certainly can have no personal object in advocating the use of antiseptics, and when he throws the weight of his mature judgment and great experience in its favour it may well make us hesitate before we set aside at the dictum of some zealous, though we fear not judicious, opponents, a system to the value of which such a body of impartial evidence has on all sides been given. To the use of the spray Mr. Wells points out some objections which all practical surgeons are well aware of; but this is only a part of the system, and though we should be slow to omit it altogether, we agree with the author that in ovariectomy it has its disadvantages. Septicæmia is the cause of the majority of deaths after ovariectomy, and everything which can be done to lessen the chances of its occurrence should be adopted, but Listerism must not be exclusively relied on, and we are of opinion that with respect to ovariectomy its value has been to this extent overrated, that it has led to the abandonment of drainage in cases in which this should have been employed. While practising Listerism ourselves we cannot, in ovariectomy, at least rely on it as being an absolute safeguard against septicæmia.

Mr. Spencer Wells, in common with most operators, has abandoned the use of the clamp, and now returns the pedicle, when ligatured, into the abdominal cavity. He believes that Listerism has enabled this important change in practice to be adopted with safety. We think, however, that that system can hardly be credited with this improvement, and we know that Mr. Keith, of Edinburgh, who has ceased to use the spray, still practices the intra-peritoneal method with safety.

But after all, the most interesting, if not the most important, part of the work is that which treats of the "Recent Extensions of Ovariectomy." The first in order of time of these "extensions" is the so-called "Normal Ovariectomy" of Battey, "whose object was to bring on old age," or, more correctly, premature cessation of the menstrual function in women in whom that function was malperformed. On this subject Mr. Spencer Wells writes with his usual good judgment. He says: "I accept the principle, but see that the operation has a very limited application, and that the conditions justifying such an operation are exceedingly rare is evident from the fact that, since his enunciation of the principle upon which he proposed to act, Battey has only found fifteen cases in which he could see reason for carrying it into practice." When we hear, then, of a local practitioner in England performing this operation seventy or eighty times in one year we feel that the "abuse" of it, which Wells feared, has become a reality.

The chapter on "Uterine Tumours" is a very instructive one; it is but a short time ago since the removal of these by the abdominal section would have been considered entirely unjustifiable, yet Mr. Wells has himself operated on such seventy times—thirty-nine of these being cases of removal, and thirty-one of partial removal, or of exploratory incision. The mortality among these is large, but there can be no doubt but that in cases in which life is endangered the operation is justifiable.

The last chapter is "On Partial Amputation and on Complete Excision of the Uterus" the author is evidently not in favour of excision of the uterus in cases of cancer, and in this we agree with him. It is seldom the disease is recognised till it has extended to the adjacent parts, and then it is hopeless to attempt an operation; but our personal experience leads us to the conclusion that cancer attacking the fundus of the uterus is not so rare as has been supposed, and that with the improved means of making a diagnosis now at our disposal, we believe that this form of the disease will be more frequently recognised and the operation more frequently performed than it has hitherto been.

The whole work is written in a simple and clear style, abounds in clinical records of plain and unvarnished facts, and is worthy of the attentive perusal of all operating surgeons, as well as of such specialists as practise ovariectomy.

Correspondence.

RETENTION OF PLACENTA FOR FOURTEEN WEEKS AFTER ABORTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to a case of retained placenta published in your issue of August 30th, under the head of "Clinical Records," I have since received a letter, from which I send the following, with the explanation that something in my report has been supposed to reflect injuriously on the medical gentleman previously in attendance on the case. The letter says: "On March 4th I was summoned to see Mrs. G. I made an examination and found a small body protruding from the os, but as it still adhered I waited till the next day, when I introduced my finger and succeeded in detaching and removing all that the uterus seemed to contain. There were no signs of the foetus, nor did I succeed in eliciting anything which would have led me to conclude that I had any other than a very early ovum to deal with. It was evidently Mrs. G.'s intention to mislead me from first to last, and I certainly had no reason to suppose that I had to manage a case of abortion at the 10th or 11th week."

Signed,

THE "HOMŒPATH" IN QUESTION.

I feel constrained to ask you to insert this explanation as a matter of simple justice to the "homœopath in question."

I am &c.,

J. E. BURTON.

64 Rodney Street, Liverpool.

CORONERS AND MEDICAL CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am obliged by your insertion of my letter, and trust you will allow me to make some further remarks upon your note and Mr. Malcolm's observations.

I have never contended for the "necessity of holding an inquest into every uncertified death." For I have shown medical certificates to be given improperly—i.e., coroners' cases; and there may easily be cases, though no surgeon has attended, which do not fall within the definition of coroners' cases.

With respect to Mr. Malcolm's statement that a number of cases were "inquired into, but no inquests held on any of them, the coroner being satisfied in each case the death occurred from natural causes," I must again deny Mr. Malcolm's right to dispense with a jury and make inquiry himself, or to do more than ascertain whether the death was violent, sudden, non-natural, or suspicious. If it was, the coroner has simply to discharge his duty, whatever anyone may privately tell him as to the likelihood of there not having been foul play.

It has been truly said that no office or institution can fall except through the fault of those responsible for managing it; and I fear our own office is in danger from this cause.

I presume the cases in which the coroner's proper duty has been omitted are such as these:—Children found dead in bed, or dying suddenly in their mothers' arms, or from burns or other so-called slight injuries; persons dying from natural disease aggravated by want, exposure, removal, surgical operations, or want of medical attendance; or from fever due to foul smells, &c.; not to speak of cases where within twelve months there was some injury developing into pneumonia, for instance.

In all these cases it is easy for a coroner, by having a private conversation with some person or persons who want to prevent an inquest, to "satisfy" himself that there is nothing wrong. But it is self-evident that the coroner's refusal to make such cases a matter of open public inquiry must encourage all who are connected with similar cases in carelessness or neglect.

A solicitor in full practice who is applauded by his council, or who is paid by salary, for not "holding unnecessary inquests" may not unnaturally pass what is clearly a coroner's case under such circumstances. I am satisfied by five and thirty years' experience, both of the public protection of obeying the law strictly, and of the public danger of neglecting it. I may add that although a criminal verdict is seldom given, the presentment by a

jury of past neglect or of due precautions for the future, published with the case itself, is productive of much good, which is lost on the coronor's "private conversation" system.—Yours faithfully,

EDWARD HERFORD,
H. M. Coroner, City of Manchester.

Obituary.

DR. IRWIN, OF MONAGHAN.

WE regret having to notice this week the death of Wm. Nassan Irwin, Esq., M.D., which took place at his residence on Tuesday week. Dr. Irwin has been a resident in Monaghan for the past nineteen years. Previous to coming to Monaghan he had an extensive practice at Castleblayney, where, for over twenty years, he practised professionally. Dr. Irwin was appointed surgeon to the Monaghan Militia in 1854, which appointment he resigned about two years ago. He gave up practising when coming to Monaghan to reside in 1863. Dr. Irwin was a man of independent means, having considerable property in the counties of Leitrim and Armagh. He died in the 76th year of his age.

Notices to Correspondents.

65 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MEDICAL PUFFING.—Our attention is called to a very gross and discreditable puff of Dr. Baptist Gamble, of Enniskillen, which appeared in the local paper last week. It appears that Dr. Gamble trephined a patient, which very insignificant surgical feat the local penny-a-liner calls an "extraordinary surgical operation." All the details of this splendid achievement are given in anatomical phraseology, as if there was something worthy of notice in this trifling performance. If Dr. Gamble is guilty of this nauseous advertisement he deserves the strongest professional censure; if not, he ought to sue the local paper for the damage done to his character by the puff, and to take care that his assistant does not in future supply reporters with details of every minor operation he performs.

MR. MAKUNA.—The communication has been put forward for publication; proof will be sent you in due course.

AUTOR OPUS.—We are extremely flattered by your offer, which, however, it is quite impossible that we should accept, the pressure on our space being too great to allow of publication of any but purely medical essays. The papers have been sent.

MR. CHERRY.—You will probably alter your opinion when you have obtained further experience of the use of the instrument. It is a little difficult to manipulate at first, but when once employed with facility none will compare with it for excellence of result. Prepared sheets for reception of tracings are sold by most instrument makers.

R. S. H.—The Society's meetings begin in October, and run on till the end of May. The Clinical meets twice a month—on Friday evenings. You will find no difficulty in being admitted as a visitor to one of the meetings; if you apply to the Secretary on the evening you wish to attend you will be courteously and kindly received.

DR. JONES (London).—The Membership of the Royal College of Physicians of London is accessible to you, but only after examination, and the classical part of it is a *sine qua non*. We do not think your proposal would be entertained for a moment.

DRESSER.—If you can support your statement with facts the disgraceful proceedings shall be fully exposed in our columns. The matter, however, is one of such gravity that nothing less than absolute and unmistakable proof will suffice; and unless you can produce it to complete satisfaction, it will be useless to proceed further. We do not doubt the occurrence; indeed, we know it to have frequently been so, but we have never yet been able to fix the blame in the right quarter.

THE ODOUR OF HELIOTROPE AS A NARCOTIC.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Having undergone a long illness of gastric fever, avoiding narcotics in the shape of opiates, I steadily refused to yield to my medical adviser this mode of obtaining relief for feverish sleepless nights. In lieu thereof, I desired that a small bunch of heliotrope should be placed in my bedroom at night. The result was, that I slept the rest of Nature every night. For a week I had a fresh bunch sent by my gardener, and for the rest thus obtained to recoup my shattered health I attach to the odour of this plant. This may be worth knowing, as it is generally thought the odour of flowers at night is not healthy.

St. John's Wood, N.W.

Yours truly,
M.D.

MR. WOMACK.—Thanks for forwarding communication; it shall receive early attention.

IMITATIONS OF COFFEE.—In the new Customs and Inland Revenue Act of this year, the sale of imitations of coffee and of coffee-mixtures are made subject to certain conditions, one of which is that the packets are to contain an exact number of quarters of a pound, and another is that a label shall be affixed to each packet, denoting the proper names of the substances of which the mixture is composed. The penalty for infringing the Act is forfeiture of the article and a fine of £20. But it is declared that the Act is not to affect any statute relating to adulteration of food.

DR. A. R. E.—The alterations do not come into force until November; write to the Secretary of the College on the second point of inquiry, as we have no information to guide us in the matter.

DR. S. B. B.—It would be impossible to mention all, and partial lists published by contemporaries are manifestly incorrect and unfair. We do not, therefore, propose devoting space to the subject, preferring students to choose for themselves or take the advice of their teachers.

AGED IN THE SERVICE.—We cannot suggest any formality you have not already gone through; your impatience for a definite reply to your application is reasonable enough; but you must allow something for the red-tapeism inseparable from official work. We opine there can be no doubt as to your superannuation.

A MEDICAL WITNESS.—The fee allowed to a medical witness in a recent similar case was £2 2s., with 15s. for the night's hotel expenses, and travelling expenses in addition.

THE DALRYMPLE HOME FOR INEBRIATES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In his second Annual Report, the able Inspector of Inebriate Retreats strongly urges the need for the opening of the Dalrymple Home for Inebriates. Though indefatigable in their efforts, the Committees have received very limited pecuniary support. They, however, hope to be able to commence operations before the end of the year. The triumphant progress of temperance missions is daily recorded by the Press, and it is to be hoped that the unselfishness and devotion which ought to be the motive power of such a crusade will be attested by liberal financial support to the projected Dalrymple Home as an attempt at the reformation and cure of the many habitual drunkards whose whole system has become so diseased by alcohol that absolute seclusion from temptation is essential to restore their shattered nerves and their utterly broken-down will power. Among the officers of the proposed home are the Archbishop of Canterbury, the Duke of Westminster, Lord Shaftesbury, Sir Thos. Watson, Sir Henry Thompson, Dr. Andrew Clark, and Dr. B. W. Richardson. £3,000 is still needed. Donations, also annual subscriptions, will be thankfully received by the Chairman, Canon Duckworth, Dr. Alfred Carpenter, J. P. Crodon, and your obedient servant,

NORMAN KERR, M.D.

Hon. Sec., Dalrymple Home.

42 Grove Road, Regent's Park, N.W.

Vacancies.

Downpatrick Union, Portaferry Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 20th.

Glenfies Union, Dungloe Dispensary District.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Sept. 20th.

Lisamore Union.—Medical Officer for Workhouse and Fever Hospital. Salary, £100. Election, Oct. 4th.

Northampton General Infirmary.—Physician. Applications to be forwarded to the Secretary not later than Oct. 27th.

Radcliffe Infirmary, Oxford.—Resident Medical Officer. Salary, £150, with board and residence. Applications to be sent to the Secretary by Sept. 30th.

Winchcomb Union.—Medical Officer. Salary, £65. Applications to be sent to the Clerk not later than Sept. 22nd.

Births.

INGHAM.—September 2, at Speranza, Dalkey, the wife of Dr. Ingham, Medical Officer, Cappaduff Dispensary, co. Mayo, of a daughter.

SPENCER.—September 7, at Albion Road, London, N.E., the wife of E. R. Spencer, M.R.C.S., of a son.

SEMON.—September 9, at 59 Welbeck Street, London, W., the wife of Felix Semon, M.D., M.R.C.P., of a son.

Marriages.

MURRAY—MACKAY.—August 30, at the Cathedral, Inverness, R. D. Murray, M.B., Surgeon H.M. Bengal Army, to Mary M'Innes eldest surviving daughter of Deputy Surgeon-General Mackay M.D., H.M. Indian Army (retired).

SOUTHAM—HUGHES.—September 7, at the parish church, Staverton Devon, F. A. Southam, F.R.C.S., of Manchester, to Amy, daughter of the Rev. J. B. Hughes, Rural Dean, of Totnes.

Deaths.

IRWIN.—September 5, at Tirkeenan, Monaghan, William Nassan Irwin, M.D., J.P.

KINCHELLA.—August 27, at Kilkenny, Lewis Chapellier Kincella, M.I.

MULLIN.—September 1, at Fethard, co. Wexford, Esther Jane youngest daughter of Peter Mullin, M.D., of New Ross.

RAYNER.—September 8, at Birstall, near Leeds, Robert Rayner M.R.C.S., aged 57.

SHAW.—August 28, killed in the engagement at Kassania Loch, Surgeon-Major George Shaw, A.M.D.

SPENCER.—September 2, at his residence, Burton Port, co. Donegal, John Alexander Spencer, F.R.C.S.I.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 20, 1882.

STUDENTS' NUMBER.

PREFATORY.

CONTRARY to expectations expressed in the Students' Number of the *Medical Press and Circular* for 1881, we are no nearer solving the great problem of medical reform at this moment than we were twelve months ago. It is true a certain amount of energy in this direction has been shown both in the appointment of a Royal Commission and the issue of a report by that body, but it would be premature to infer from this that we have really advanced very much farther on the path of improvement. Whether the coming year is destined to witness the introduction of radical changes in the mode whereby candidates for the medical profession are admitted to qualification, it would be rash, indeed, to prophecy. If we would accept the dictum of the most capable judges of the position, we should hesitate to expect any sweeping modifications; and more especially since the remarkable document issued by the Royal Commission includes a variety of independent opinions on the main points for consideration, and the points, too, which, from an educational aspect, are of the highest importance.

Disappointingly slow, however, as the progress towards reform has been, there are not a few indications to encourage hopes of substantial amendment of existing defects at no very distant date. If it does no more than keep alive an interest in the question, and enlarge the circle of those who take intelligent cognisance of it, the agitation in favour of change cannot fail to be productive of good results; and to the extent that general sympathy is excited in the ranks of the profession in behalf of reform, will success attend the efforts of those who maintain the demand for it. As matters are at present, we have to repeat in great measure the substance of remarks made in preceding years, in pointing out to intending medical students the course they must pursue with a view to joining the profession they have chosen; while, at the same time, we offer such advice on certain details connected with the calling they embrace as may enable them to avoid mistakes which, once committed, it may be difficult to escape the consequences of.

WHO SHOULD BE MEDICAL STUDENTS.

The late Professor Rolleston was a strong advocate of the principle of selection applied to candidates for the medical profession, and Sir William Gull at the present time reflects similar opinions in the demand for an "intellectual test" in respect to medical students. Each year new burdens are laid upon these students, both by reason of the ever-increasing ground over which the field of medical study extends, and through the constant additions thereby made to the requirements of examining bodies. There is

this peculiarity also about such studies as are included in the medical curriculum, that though they may be easily mastered in the abstract by dint of sheer perseverance, yet it is only a certain class of mind that can successfully appreciate the facts that constitute the main teaching of the wards, a right understanding of which alone enables the student to become an able practitioner. Hitherto the friends of intending students have, as such, paid little attention to any questions of this nature; they have not discussed the likelihood that the destined physician or surgeon may be eminently unfitted to prosecute the labours that will fall to his lot; that his capabilities may be opposed to all chance of successful practice; and that, in his own interest, almost any profession but medicine would have suited him infinitely more advantageously, and with the performance of infinitely better and more serviceable labour to his fellows. It is to this want of perception that we are indebted for the presence in the profession of innumerable unsuccessful men. Often enough they are eminently conscientious, industrious, and well intentioned, but lacking the indispensable qualities that go to make up a skilful practitioner; they plod wearily through life, unrecompensed, and, alas! too frequently unhappy. Unfortunately, also, we cannot even now put into set form of words rules for guidance in deciding on the possession of requisite endowments in any particular case. We recognise that successful practitioners possess certain well-marked characteristics, and we can easily enough associate their success with such marks of superiority; but it would be difficult to say what traits in a youth will develop into them until we see him at work amidst cases of illness in the wards or out-patient room. Even the most ordinary practitioner requires to possess certain powers of mind in order to be of service to his patients; and it seems but wise that some consideration should be given to the question whether the would-be medical student offers evidence of exhibiting capacity for the profession he is about to enter on.

Bodily physique, too, is a detail in this connection not enough regarded. The life led by a medical man is at the best a trying one, and when his lot falls in country districts he must needs be strong in health to overcome all the difficulties of his position. Not a few young men yield early in their career to the strain put upon them by professional work, a strain they have been unable to support; and within our own personal experience cases have occurred in which most promising lives have been early sacrificed in this way. It should, therefore, be always a point for anxious determination whether the incipient student bids fair to grow into a toil supporting practi-

assert distinctly also that, so far as my experience goes, sterility is the constant result. The affection, is moreover, in many cases, perhaps the majority, exceedingly difficult of cure, and for this simple reason: it is not only the uterine cervical and superior cavity which is affected, but the tubes likewise. A temporary cure by local applications to the uterus may be effected in the cavity, and for a few days a practitioner may believe he has cured the patient. Perhaps, a fortnight later, he is mortified in finding his patient as bad as ever. There has been no cure of the catarrh of the Fallopian tube, and, through the continuity of surface, the uterine mucous membrane has been affected.

I believe one of the reasons why peritonitis is not more common in these cases is that the expulsive or downward action of the cilia of the tube directs the unhealthy secretion into the cavity of the uterus rather than into the peritoneum.

I think it will facilitate the description of the points I wish to bring especially before your notice if I speak of this disease under three varieties, although they are but stages of the same disease—namely, 1. Where it is confined to the cervix; 2. Where it extends to the superior cavity of the uterus; 3. Where it reaches the Fallopian tubes and peritoneum.

1. Let us speak first of the cervical variety. On examining a woman affected with this form of tenacious leucorrhœa we generally find an accumulation of mucus around the cervix. This is generally removed with difficulty; but even then a more or less thick cord of the same secretion projects as a piece of string from the os, and cannot be detached. Even if a piece of thick wire or a sound, around which some medicated cotton has been wound, be introduced into the uterus, it cannot be so removed. More and more seems to have accumulated above, and the mucus is as tenacious as ever. It is rare, however, that in such cases the operation can be done without exciting pain just as you pass the internal os, and sometimes higher up. The severity of this pain varies. In more chronic cases it may be slight; in others, and in these generally the dysmenorrhœa is very troublesome also, it amounts to an agony, which lasts for hours afterwards. I may here state, however, as useful, not only in these cases, but in others where the passage of the sound is attended with pain, that the injection, *per vaginam*, of water as hot as the patient can properly bear it, is the most effective way of checking or relieving it. The moment the internal os is passed, the exact pains which the patient is accustomed to have during a period are reproduced. The patient, indeed, will spontaneously exclaim, "Oh, you are bringing on all my poorly pains!" The point of starting the pain is, therefore, probably at the internal os. I have also noticed that in a large proportion of cases uterine version or flexion exists, especially anteversion; but there can be no doubt that the internal os, by reason of the pain, is the seat of spasm, which, for a time at least, precludes the passage of the cervical fluid into the superior uterine cavity. This spasm, as well as the version where it exists, is in a measure a preservative action, and often prevents the development of the second stage.

If we now look to the mechanism of the production of this affection, we may trace some of the concomitants which render it so permanent, especially with married women, or women having relations with men, and which make it so obnoxious to treatment. These are mainly two:—1. Direct suction upwards of the diseased fluid by the uterus; 2. The natural pressure downwards, and partial opening of the os during copulation.

I have elsewhere shown that, by means of a very simple instrument, we may prove that there exists a power of suction upwards by the vagina and uterus during expiration, which is entirely due to atmospheric pressure. Take an ordinary speculum; close the uterine end by a thin membrane, and the other end by a cork through which a glass tube bent at right angles passes, and which is of some length; if this speculum be filled with water,

which is allowed to extend also up the tube, at each inspiration the patient makes the water will rise in the tube, while with each expiration it will fall—i.e., there is a fall of the water in the tube. The mechanism of this change is too obvious to require comment. In some women, owing possibly to some peculiar folds of the mucous membrane of the vagina, which acts in a valvular manner, air is being continually sucked up, and at last fills the vagina till it provokes an expulsive effort, and the air is forcibly propelled outwards, and sometimes with a noise similar to flatus expelled *per anum*. I believe it is an operation very analogous to this which takes place in *utero*, through some condition, also of a valvular character, in the external os which causes vaginal fluids to enter into the uterus during expiration. It is, perhaps, for this very reason that, at the critical moment of the orgasm induced by sexual intercourse, repeated and sudden expirations occur, which facilitate the upward passage of the semen into the uterine cavity.

Dr. Matthews Duncan has referred this suction upwards of vaginal fluids in *utero* rather to a reverted action of the muscular fibres of the uterus; and in this manner he explains the occasional drawing upwards of intra-uterine pessaries and their enlarged discs at their distal end right up into the uterus, which often taxes disagreeably the practitioner's ingenuity to get them out again. I have also had some of these unpleasant accidents to meet. Nor is this confined to the uterus. In cases where an artificial anus has been made, I have seen large pieces of lint and cotton sucked up and disappear altogether, and never found again. Nay, more; when an anus was made in the groin, and an ivory tube with a large cap placed in it, this has also been sucked up and disappeared. In one case where this occurred, the patient is still living. Here, perhaps, there may be some reversed peristaltic action to account for it. Still it seems more rational to attribute, at least in the uterus, these effects rather to propulsion upwards by atmospheric pressure during expiration: first, because it necessitates the dilatation of the external os, which would imply an uterine contraction, which, we should suppose, would expel the contained intra-uterine pessary; and, secondly, because the uterine cilia have also an action in the expulsion of contained fluids. The moment, however, we explain it by atmospheric pressure forcing fluids upwards during expiration, and some accidental valvular action of the mucous membrane at the os uteri, the result is obvious. That such valvular action of folds of the mucous membrane does take place, is often made sufficiently palpable; but, conversely, when we try to introduce a sound, in some cases, we are prevented altogether by some fold of mucous membrane, and also by the result often noticed, and well instanced by Dr. Barnes, that, when the external os is cut a large quantity of mucus, previously retained, obtains at once a free exit.

There is another cause also operative in such cases; the fact that, during intercourse, the uterus is forced downwards to meet the male organ, and probably the os undergoes a sort of dilatation at the same moment, both of which circumstances mechanically facilitate passage of acid fluid upwards in the uterus. The way in which gonorrhœal fluid may thus pass into the uterine organ is sufficiently obvious.

Be it, however, gonorrhœal or other acrid vaginal fluid, it is equally obvious how, once in the cervical cavity, it will act as an irritant. It is well known that the vaginal secretion is acid, sometimes intensely so, whereas the uterine secretion is alkaline and markedly so. When an excess of acid fluid is thus sucked up in *utero*, of itself it will produce irritation leading to inflammation of the mucous membrane; and secondly, the contents of the uterus, now being acid, will kill any spermatozoa which are present, and so sterility follows as a matter of certainty. In these cases, the dysmenorrhœa is mainly due to obstruction at the external os, and the pain is chiefly referred to the lowest parts of the pelvis.

It was the examination of many of these cases that led

me to conclude that, in a large proportion, the fluid sucked up did not pass the internal os, but was by constriction there prevented from going beyond. I have been met by the statement that there are no special circular fibres here forcibly to close the opening. All we notice are merely a few fibres which here decussate. I do not in any measure question the anatomical fact. But I am certain it is not a pathological fact. Like muscle everywhere when frequently taxed, it becomes hypertrophied, and then it acts distinctly as a sphincter. I have verified this over and over by the use and retention of caoutchouc intra-uterine pessaries, where at this point there has been left a very distinct circular impression. And more than this, such constrictions may under disease take place elsewhere within the uterine cavity, especially in certain forms of version or flexion, as these tubes prove. This is possibly sometimes the seat of ulceration, a state of things being here produced which is analogous to fissure of the rectum; as, when touched with the sound, not only is the pain intense, but blood follows its use.

Certain it is, however, that constriction does occur at the internal os, and here we have the explanation of the intense pain sometimes experienced by women. As you pass the sound through the internal os you at once provoke a spasm, which continues for a time, and not unfrequently you find your sound comes out bloody, exactly as it does in some cases of stricture of the male urethra, so forcible has been the local resistance. It may be that there may also exist at such parts slight ulceration.

2. Sometimes there is not such a complete closure or resistance at the internal os, or the cervical cavity is so full and dilated with muco-pus, that the fluid, not being expelled downwards, is forced up into the upper uterine cavity of the uterus, and we have the second variety of tenacious gonorrhœal uterine leucorrhœa. Sooner or later this result follows, and gradually but completely the uterine cavity becomes filled with fluid. The symptoms now are altogether different. They are, in a few words, those of greater and higher local uneasiness; sometimes phenomena of spurious pregnancy, followed often by symptoms not unlike those of miscarriage; but I shall again refer to them. Exacerbation of pain recurs not only at the onset of menstruation, but at other times, when the contained fluid, whether catamenial during menstruation, or muco-pus during the interval, is forcibly expelled by a powerful uterine contraction which overcomes all before it, and relief follows. Fortunately, the disease does not always extend beyond. But sometimes it does, and then the case is one of very serious import, at best one of confirmed invalidism. This constitutes the third variety, where the Fallopian tubes become inflamed, and even perimetritis may occur. In the worst cases we may have those results insisted upon by Noeggerath, when a few drops of the inflammatory secretion of the tube escape, possibly by a contraction of the tube giving rise to perimetritis, and sometimes rapid and fatal acute peritonitis. Fortunately, in this country at least, this unhappy complication is not common. It cannot be said, at least in Great Britain, if it can be elsewhere, that all our young married ladies are diseased by their husbands, so that young ladies are afraid to be married, because they know that all their married acquaintances were made ill directly and never again recovered.

The dysmenorrhœa in these cases is very severe, accompanied with general uterine pain, tenderness reaching high up, and very aggravated.

Let us now distinguish how far from symptoms we may diagnose these three different varieties. I have already spoken generally of the general symptoms. We have considerable assistance, as I have shown in my paper read before the Obstetrical Society (*Transactions*, vol. xii., p. 136) "On Fundal Endometritis," by the special localisation of the pain which is influenced by the nerve-distribution. In the cervical variety, the pain is referred to the lower part of the sacrum, the lower part of the pelvis, where there will be heavy, dull pain, sometimes reaching as high as the groins, but not higher. The vagina also,

especially at the upper part, feels sore, so that connection becomes sometimes very painful, or, if pressure be made with the finger on the cervix, it gives pain. Once become chronic, however, all these symptoms are greatly diminished in intensity. In the second variety we have pain extending higher up, more marked just above the pelvis and pubes, markedly in the groins, and extending down the thighs, generally the left. Occasionally it extends, as in ordinary cases of fundal endometritis, up to the waist, in the region of the semilunar ganglion, and over both ovaries, specially the left. In the third variety the symptoms are those of perimetritis or peritonitis, which need no special description, except that I may remark that I have noticed in several of those milder or more chronic forms, where neither perimetritis nor peritonitis existed, that on pushing the finger high up on either side of the uterus, or with the index finger placed there, making pressure from the abdomen, I produced intense pain and a sickening sensation even in those cases where there was no enlarged ovary, although in some I have noticed these organs also enlarged and very painful.

So much for the pain. But in the second variety it often occurred that sudden relief was obtained, at least for a time, by a forcible expulsion of the uterine contents by a sort of labour-pain. In these cases also, except where the disease had lasted many years, and sensation, as if it had worn itself out, was diminished, intense dysmenorrhœa was present, and the pains extended higher in the abdomen, according as cervix, fundus, or tubes were affected. I should remark that the breasts not only swell and become uncomfortable in these cases, as is commonly observed during menstruation, but become exceedingly painful, constituting mastodynia, which even persists after the period, and occasionally gives rise to hypertrophy of the organ. In these cases the second variety is always present.

Treatment.—For a long time I was greatly puzzled with these cases. If I cured them for a time, they were sure to recur. It is so even now with a few cases, and especially with those which include the third variety. The principles of treatment indicated here are three-fold; first, local antiphlogistic measures and other general agents to relieve the local congestion or inflammation; second, free exit to all contained irritable fluids, and the prevention of the suction upwards of the same; third, local appliances to correct the diseased action of the mucous membranes, and to keep the cavities patent. It is my conviction that the cases are very few and far between, which will yield unless these three measures be combined; and even in ordinary cases of leucorrhœa of an uterine origin, where the tenacious mucus does not exist, the same treatment is most efficacious.

First, of the local antiphlogistic measures and other general agents to relieve the local congestion or inflammation, blood-letting by means of leeches applied to the cervix uteri is both safe and effective. It is, in fact, a *sine quâ non*, the backbone of success, and much to be preferred, in my estimation, to the lancet. The uterus in these cases is more or less hardened. Fibrinous deposit has, in measure, taken place in its parenchyma, and blood will not flow, though the cervix be pricked heroically and extensively. The hysterotome, or cutting the os on both sides from within, if a knife were used at all, limiting the cut to the cervical cavity, was the best way of doing it. But leeches are to be preferred. The very suction of the leeches brings down the blood, favours the downward course; and, when they fall off, the oozing of blood continues. In a plethoric woman (six leeches at a time), the leeching may be repeated half a dozen times at least. It is the best preservative against subsequent inflammatory complications. If there be also much abdominal pain, then leeches may also be applied on the abdomen; but here I think blisters, or iodine paint applied to the belly, and frequent saline purgatives with anodynes, and alterative doses of mercury, are the best adjuncts.

The patient thus prepared, we are in a position to put in operation the second mode of treatment, viz., to give a free exit to all contained irritable fluids, and to prevent the further upward suction of the same. This, after all, is one of the first principles of surgery. If matter be cooped up in any cavity we must let it out. If the external os be small, and its action valvular, as before explained, it must be cut through. Mere dilatation, without a bougie or intra-uterine pessary, at best can only have a temporary effect. Nor have I ever seen the slightest danger occur from cutting the external os in a patient previously prepared by the measures before indicated. A pair of scissors, a bistoury, or Dr. Barnes's instrument, is sufficient. Precisely as when we cut a fissure in the anus, the parts are at rest. No more suction can take place upwards, and a free exit is given to all contents. We have, in fact, one abscess with a free external opening. The cervical cavity can now be locally treated by local agents, and its diseased action cured. A number of these are in daily use. A small stick of nitrate of silver may be advantageously left in the cavity, which will often correct and change the acrid secretion, and recovery may follow. Another agent is pure carbolic acid, placed on a piece of wire previously covered with cotton-wool, and afterwards dipped in crystals of iodoform. This last is very successful, and, moreover, relieves pain. I have sometimes used iodine paint, as advised by Dr. Wynn Williams, made by mixing iodine, iodide of potassium, water, and spirit, in equal parts; but I have not found in my practice anything as a local agent so successful as the iodoform and carbolic acid conjoined.

When, however, we have to treat the second variety of this disease, we tread upon more dangerous ground. It should be stated unequivocally that, if local remedial measures, such as the hysterotome and intra-uterine pessaries, be employed before full and effective antiphlogistic regimen has been premised, inflammatory complications of serious character, and death by septicæmia, may follow. If this regimen, however, have been observed, it is comparatively safe to cut the internal os by the hysterotome, or dilate by a sea-tangle or sponge-tent. The morbidly contracting decussate fibres of the internal os must be overcome. If we cut, it is wise to let the patient bleed awhile. If the bleeding seem too profuse, then it is wise to introduce a small piece of sea-tangle; but one important caution should be remembered. It should not be straight; it should have the exact curve of the uterus. To attempt to put a straight one in mars and injures the cut position, and is favourable to the development not only of severe pain, but of inflammation. For this purpose I invariably use sea-tangle of various curvatures; or if I use a sponge-tent, I pass through it a piece of steel wire, which I then bend to the curve required. Sometimes, by pulling down the uterus a little way, the tangle or tent is more easily introduced. But the uterus should not be pulled down far or violently, for peritonitis may be the result. Be it tangle or tent which is used, another precaution is necessary. Surround either by a little cotton-wool, and dip it in a solution of glycerine and iodine. This is an antiseptic agent which prevents subsequent poisoning.

Sometimes, however, notwithstanding every care, the pain produced is so great, that neither tent nor tangle can be borne. We must then proceed another way. If the pain and bleeding persist, inject into the vagina water as hot as the patient can bear. This almost invariably arrests them both. If the bleeding persist, then I plug the vagina only. An anodyne suppository helps the patient, if used in addition. Within forty-eight hours, all plugs being removed, I then insert into the uterus a small taper, such as I show you; it is covered with cotton, shaped to the cavity, dipped then in carbolic acid, introduced, and left *in utero* for about twelve hours. It is seldom that this process need be repeated. The uterine tenderness generally disappears, and a

large sound can be introduced without pain. The case may be left then, and will often do well; but I prefer using an intra-uterine pessary, one of the various forms I now show you, and which are for the most part well known to the profession. I have kept in the cautious ones I show you for a year; the combined Hodge's and intra-uterine pessaries which I described at Bath before the Association, for six or eight months. The mucous membrane then assumes a healthy character. The catamenia are copious and painless often from the very first, generally by the third subsequent catamenial period. The dysmenorrhœa and the tenacious uterine leucorrhœa alike disappear.

Lastly, as regards the third variety; in the more acute forms, the antiphlogistic treatment should be fully and heroically carried out at the onset, if we be fortunate to see the case early. Local leeching to the cervix and over the abdomen, followed by blisters, are here indicated; but even general bleeding should not be feared if there be much pain. Calomel and opium in half-grain doses should be given every three hours; and five minims of tincture of aconite, two drachms of liquor ammoniac acetatis, for every two hours, till temperature and fever abate. This treatment may prove effective. More often, however, the disease assumes a chronic form.

I have noticed that, in cases where the early symptoms have been of this serious import, once the chronic symptoms have occurred, the treatment recommended for the second variety has altogether cured the disease; possibly by insuring a free exit of the contents, possibly because the intra-uterine pessary, if *in situ*, precluded the influence of atmospheric pressure of suction upwards; possibly because an uterine pessary always favours a copious flow of catamenia, and thus relieves all local congestion. And what is more agreeable to the sufferer, the matrimonial alliance, which had hitherto proved an occasion of sorrow by the disease produced, has passed into one of joy through the birth of a child.

THE EXPEDITIONARY FORCE FROM INDIA TO EGYPT IN 1800.—II.

By Surgeon-General C. A. GORDON, M.D., C.B., Q.H.P.

CONTINUING remarks already made in the *Medical Press and Circular* on the Indian expedition to Egypt in 1801, it is well for statistical purposes to give the numerical strength of that force. The first portion of the contingent sailed from Bombay on December 28, 1800, but did not reach Suez until the end of April, 1801, this great delay having been due to adverse winds in the Red Sea. Shortly afterwards the remaining portion of the force followed, and was joined by artillery, cavalry, and infantry sent from the Cape. The entire force numbered 3,759 Europeans, and 4,127 Asiatics, making a grand total of 7,886. It continued in Egypt till June, 1802, that is, a period of fifteen months. As already stated it had no fighting to do, so that the casualties which occurred were altogether due to endemic causes, and accidents incidental to ordinary service in that country. These particulars premised, records before us show that among the Europeans there occurred during the time in question 315 deaths; that there were sent away to India and England as invalids 117; equal to a ratio per 1,000 per annum of 105 under the former head, 37 under the latter, and to a total ratio of loss by both causes combined of 142. Among the Asiatic troops the deaths numbered 377; the invalided 41; equal respectively to 114 and 12, and a total ratio of loss of 126 per 1,000. So far, therefore, the results obtained show, on the occasion referred to, that, whereas the ratio of deaths was greater by 9 per 1,000 among the Asiatics than among the Europeans, that of invaliding was only one-third of what it amounted to in the latter; yet that the

"wear and tear" of the force by disease was so nearly alike in both classes that it amounted only to 16 more in the one than in the other. The balance, small as it was, was against the British.

To quote the words of Sir James McGrigor, from whose "Sketches" much of the data for the present remarks are gathered: "Perhaps it may be thought that I have descended to a great degree of minuteness. However, I conceive that from the facts stated important and useful deductions may be made. I think it a matter of regret that such journals are not more frequently kept; with a little industry on the part of the profession they might always be so. Had such records been always faithfully kept, many practical points would not, as they now are, be involved in doubt and uncertainty." (Page 56). The words quoted were printed in 1804.

With reference to the diseases by which mortality occurred, the statistics available show that their ratio of incidence differed to a great extent in the two classes of troops already alluded to. Taking the diseases as enumerated in the "Sketches" (Table II.), the subjoined abstract represents actual numbers of deaths by each respectively among Europeans and Asiatics, namely:—

Plague	38	Europeans ...	127	Asiatics.
Fever	18	"	92	"
Liver	64	"	12	"
Dysentery	148	"	47	"
Diseases of the	4	"	6	"
lungs... ..		"		
Stroke of the sun	2	"	—	"
Casualties and	41	"	93	"
diseases un-		"		
known		"		
Totals	315	"	377	"

In the above abstract the "diseases unknown" include casualties the precise nature of which is unrecorded, small-pox and other cases lost in the *Julia* hospital ship; also nine deaths which happened in corps previously to the surgeons taking charge of them.

Before passing on to consider the remarks made eighty years ago upon the diseases incidental at that time (shall we say only then?) to troops employed in Egypt, a few notices from the "Sketches" may serve to indicate certain points bearing upon hygiene of armies in the field that seem to have an importance of their own if considered in reference to our forces now operating there.

Although a good deal of sickness had occurred among the troops during their long voyage to Suez (this is now avoided by our modern means of transport), the general state of health was so satisfactory that "rarely indeed have troops on any expedition been landed in equally good physical condition (p. 58). When sickness attacked the troops it affected in different degrees those of the same class who came from different localities. Thus, of the artillery, the Bombay suffered the most; next to them the Royal; next the Madras; then the Bengal; and least of all the horse artillery. The prevailing diseases were dysentery and hepatitis. At one time fever prevailed among those from Bombay. The cavalry continued remarkably healthy throughout the whole period of occupation. Some of the infantry, having performed a long and arduous march across the greater desert, suffered considerably from fever, the disease terminating in hepatitis or dysentery.

Special reference is made to the 61st Regiment, on account of it having been chiefly composed of young men. When that corps arrived in Egypt it was in a high state of health and discipline. At Alexandria it was quartered in the Pharos, the locality damp, and surrounded by sea, except on the side of the mound which connects it with that city. The men became attacked with dysentery and hepatitis, and,

next to the regiment already alluded to (10th Foot) as having suffered from an especially arduous march in the desert, the 61st had the greatest proportionate loss of any in the force (p. 61 and Table II). (How very important therefore in reference to the present expedition are the particulars thus extracted!)

The 80th Regiment had come from Trincomalee. It had been quartered at that unhealthy station during five years, and had there lost many men. On landing in Egypt the regiment was very healthy (p. 61). It was composed of drafts of men from other corps who had volunteered to it after having themselves served in India "fifteen or twenty years." At Ghizeh, El Hammeh, and Alexandria they were the most healthy corps. Many of the old men suffered severely from the march to Alexandria, and especially during the cold weather; yet many others who were never free from liver complaint at Trincomalee never complained of it in Egypt. (These are also very important points, in one respect as bearing upon the views entertained now-a-days on the subject of old men, and old soldiers, in another as illustrating the very striking curative influence exerted by "climate" in cases of liver disease.)

(To be continued.)

THE CHINESE MATERIA MEDICA.

By FREDERICK NEWCOME, F.S.S.

(Concluded from page 106.)

OF animal products, musk probably stands highest in repute among Chinese doctors, but owing to prohibitive prices, the use of it is confined exclusively to the wealthier classes. For the pure unadulterated article obtained from the male *moschiferus*, or Thibet musk, from twenty to forty shillings an ounce is the common price to pay, and although the dose given is small—seldom more than half a drachm to a drachm at a time—it is impossible that the poor can afford such a luxury. Even high prices are frequently paid *wholesale* by Chinese merchants for home consumption, and this fact, viewed in connection with the average value of the musk exported to this country (during last year it was less than a guinea an ounce all round), leaves but one conclusion in our minds, namely, that the supply for this market is adulterated to a greater or less extent, despite London druggists charging for it gold price or higher. Last year (1881) the total exportation from China amounted to 1,877 catties, or say 2,503 lbs., valued at 149,780 taels, or about £41,501; in other words, the average was something like a guinea an ounce, whereas true musk always fetches from thirty to sixty shillings an ounce at Shanghai or Tientsin. Here, again, it is just possible that some of the unfavourable results attributed to musk, and its bad repute among Europeans, may have been owing to adulteration, which, as everyone knows, was, and still is, largely carried on.

Bezoar stones are equally in repute, almost fabulous sums being given for the genuine article. For *Bezoar bovine*, classified in the Returns of Trade as "Cow Bezoar," the export price varies from four to five hundred taels the catty; that is to say, from £6 to £7 10s. per ounce. Probably, however, several kinds of bezoar, including stones derived from animals of the goat tribe, are included under the generic term; but upon this point our knowledge is deficient. When such an astounding price is paid for the Chinese article by native dealers, there is little wonder if the samples that formerly reached Europe were spurious as alleged. Whether there is any great medical virtue in bezoar, or whether there is none, is a question that will probably be decided in time; but to settle the point it is necessary to examine and test the true Chinese article, which evidently cannot be sold under double its weight in gold.

The Chinese also import a considerable quantity of Indian Cow Bezoar. This, after transport to China, is

only worth about 5s. to 5s. an ounce, or [barely one-tenth] that of the genuine native article, which we have no hesitation in asserting to be one of the dearest drugs in existence. Beargall is another expensive animal product, being commercially worth some sixteen shillings an ounce in Shanghai; but for what medical purposes it is used we are unable to state. All we know is that it forms a part of their *matéria medica*, the same as the ordinary vegetable nutgalls, with which the country-side everywhere abounds.

Although allusion has already been made to a considerable number of Chinese drugs, the list is still far from perfect. Hundreds more could be enumerated, and yet our task would be incomplete. Indeed, all that can be done within the limits of this series of articles is to particularise the more important—those which play a recognisable part in the commercial economy of the empire.

In their everlasting struggle against disease, these remarkable people have evidently ransacked the whole vegetable kingdom from end to end. Nothing that afforded the least hope of relief seems to have escaped their attention, nor have the other products of Mother Earth wholly passed unnoticed. Several kinds of earth have been made to pay homage at the shrine of *Æsculapius*. One—*hoa-che*—deserves some passing comment. From this stone, or rather from this species of chalk, the Chinese manufacture their finest porcelain vases. At the world-famed factories of King-te-ching, *hoa-cho* is commonly used instead of kaolin whenever transparency is the chief desideratum, or expense but a secondary consideration. However, like many things in China, it serves a double purpose, physicians preparing from it a draught said to be aperient, cooling, and detersive. When first dug up, the stone is exceedingly glutinous, bearing a strong resemblance to soap, and from this peculiarity it presumably derives its name of "*hoa*."

Little progress has yet been made in the way of gaining knowledge of the properties peculiar to the various metals, and the less said about this branch of medical science in China the better. Excepting a few foreign preparations, with which constant intercourse with Europeans is rendering the native populations at the Treaty Ports slowly conversant, quicksilver is the only metal with which their physicians can be said to have any proper acquaintance. From early times this poison has been given by them in severe cases of venereal or scorbutic taint; but, as earlier remarked, the Chinese as a race have conceived a widespread objection to its use, alleging that it creates impotence in the one sex and barrenness in the other. As an ointment, on the other hand, it is still frequently used by native practitioners, who likewise manufacture a mercurial plaster, in the efficacy of which considerable faith is seemingly placed.

Beeswax plays a by no means unimportant rôle in Chinese medicine, forming the base of most ointments and plasters, in the manufacture of which an enormous quantity is annually consumed. So vast, indeed, is the consumption of beeswax for this purpose that one is inclined to join the good Dominie in crying "*Prodigious!*" That the Chinese should elect to use beeswax as the base for their ointments is somewhat curious, seeing how many other equally suitable substances are to be found within the borders of the empire. Among the many strange and wonderful commodities deemed of utility, silver dross may be specially mentioned. Upon the eternal principle of wasting nothing, "*Ah Sing*" converts this rubbish into a miraculous plaster—a sort of universal "*Heal all*." That this remedy possesses any intrinsic merit cannot for an instant be supposed. If any cures at all are effected by it, they may be set down to faith and imagination—two tonics of amazing potency. The "*red pills of unfailing efficacy*," distributed by the Bandcham Rembouchi to the deluded yearly flock in thousands to visit the

famous Lama College at Djachi-Loumbo, also belong to the world of superstition. These pills, it was long since ascertained, are good for little else save filling the empty coffers of this sink of iniquity, and keeping a set of idle vagabonds in luxury, while much the same remark may be made about a dozen other remedies used by the medical Lamas in the interior.

The asserted skill of these worthies is generally recognised as a pretence; but then they understand the races with whom they have to deal. So simple are the Tartars, and so exquisite is the faith they place in their spiritual teachers, that any amount of chicanery or nonsense is credited. According to M. Huc and later travellers, it sometimes happens that the medical Lama, not having at hand the specific medicine he requires, contents himself with scribbling its name upon a piece of paper. This, when rolled into the shape of a pill, is given to the confiding patient, who swallows the indigestible bolus in the full satisfaction that his stomach will derive just as much benefit from it as if he had swallowed the drug itself. Time seems scarcely to have weakened this and a score other wretched superstitions; indeed, quackery is little less prevalent in the China of to-day than in the China described so long ago by Nieuhoff and Le Compte: it still pervades their therapeutics to a vast—we may say, to an inconceivable—extent; but, in justice to this people, we must remember that quackery is equally diffused throughout all Oriental science. Even "*Westernism*" is not free from its pernicious taint. European science always has been, and always will be, subject to a certain amount of imposture; this is inevitable: but, nevertheless, many cures once used by charlatans or empirics alone are now included in the British Pharmacopœia, and this memory should render English doctors lenient in condemning as humbug all Chinese medicines. Besides facts—that is to say, excessive fecundity and comparative longevity—have demonstrated the value of some among their manifold drugs. Doubtless, many are worthless; but some must be good, and it remains for Science to eliminate the chaff from the wheat, and to ascertain which are suited to the European temperament and constitution.

Physicians are not likely to pay much attention to the wondrous stories related about cures resulting from the use of "*young deer horns*," "*crocodiles' scales*," and "*tigers' bones*"—all of which, by a stretch of imagination, may be included in the Oriental Pharmacopœia. These are probably mere travellers' tales, and, whether founded on fact or superstition, are simply charlatanism in its more brazen forms. Crocodiles' scales and a hundred other Chinese nostrums may be dismissed without a moment's consideration, but English science will do well to investigate to the utmost the several herbs most in favour. Common sense is against the presumption that herbs consumed by the hundreds of tons annually, and which have maintained their reputations for centuries, contain none of the many virtues attributed to them. To argue otherwise would be plainly illogical, else why should China be the most populous of all countries? This consideration alone, it might be thought, should dispose of all objections to properly testing these almost unknown drugs, but we fear it will not. For some occult reason, Englishmen have always felt inclined to deride China and things Chinese. Perhaps the feeling is only natural. Their stupendous conceit and strange aversion to progress early rendered them the laughing-stock of European travellers. Our two wars with them proved simple burlesques—mere holiday rambles for our soldiers and sailors—while in many other respects we have, doubtless, found these people contemptible to a degree. But in double-dealing, adulteration, cheating, and similar recondite sciences, Europe has discovered its match in the "*child-like and bland Chinese*." Herein he displays talents and intelligence of a no common order, as all who have frequent dealings with him are bound to admit. Is it not likely, then, that he may be equally

well skilled in the other Arts of Peace?—that he does know a good deal about medicine? What are the facts? What are the pro's and con's? Let us reflect for a moment.

China is credited with containing from one-fourth to one-third of the human race. True, its total area is immense; but, like the Russian Empire, the greater part is sterile, and very sparsely inhabited. China proper is not nearly so large as Russia in Europe, but it feeds a population estimated at about five times as great. Acre for acre, it is almost as densely peopled as the United Kingdom, while general provinces—each singly as extensive as England—find sustenance for three persons to its two. Even little Belgium cannot compare, in the matter of population, with such provinces as Chihili, Kiangsu, Anhwei, or Chéhkian, although their bulk is many times as great. Neither climatic influence nor personal habits, neither religious nor matrimonial customs, fully account for this preternatural fecundity, especially when considered in connection with the many adverse influences ever working in a contrary direction. From time immemorial China has suffered patiently under a long succession of plagues, pestilences, and famines. With sanitary arrangements that simply outrage all European notions of cleanliness and decency; with habits of life dirty and disgusting in the extreme; eternally scourged with cholera, famine, yellow fever, war, oppression, and a dozen other causes, this surprising people has increased and multiplied to an unparalleled extent. Half-starved, constantly afflicted with some or other disease (as with most Oriental nations, they are subject to diseases in their more active and virulent forms), in short, with every incentive to short-livedness, the Chinese, both male and female, attain to a relatively old age. Large families are common, while, notwithstanding the admitted incompetence of native nurses, the ratio of deaths during, or shortly after, parturition is surprisingly small. Hard-worked, badly fed, hovelled—not housed—and downtrodden from birth to death by the Mandarin classes, the lower orders contrive to live to ages that would render them anything but hazardous lives to assure.

Moreover, children are brought into the world in a fashion that has raised the ire of many an English surgeon, and which would inevitably destroy the life of both mother and infant were Europeans treated in a similar brutal manner. Concerning the utter incompetence of native nurses as a body there seems no two opinions. Every European doctor settled in China bears testimony to this fact, and we fail to remember seeing a single copy of the medical reports, issued by the Imperial Maritime Customs of China, wherein several illustrations are not given of their astounding ignorance. Cases of cross or hand presentation generally prove fatal, unless some foreign medical man is in close attendance. Alone by itself, this incompetence must occasion a widespread destruction of human life; but, further, the lower rank of Chinese are still addicted to the crime of infanticide, though, of course, to an extent very inconsiderable with what was once supposed. These, and many other lethal influences we could mention, tend to retard the growth of population. Yet, live as these people may, or act as they may, nothing seems to stay their abnormal fecundity.

Unhappily, we have hitherto obtained no sufficient data whereby to estimate the mean duration of native life in China, but such few vital statistics as have reached this country go to prove an average longevity quite out of keeping with European expectancy, when allowance is made for the destructive influences alluded to above. May we not fairly ascribe some portion, at least, of this result to the medicines prescribed by native practitioners? Supposing English medical science retrogressed to the bigotry, ignorance, and superstition existing in the seventeenth century, would life be nearly as long, or marriages as fruitful as now,

seeing under what different conditions we dwell? Congregated by hundreds of thousands in our great cities: what would the death-rate probably be had our sanitary arrangements and medical skill remained *in statu quo*? In a vast emporium like modern London, with breathing room utterly inadequate for its four million inhabitants, plagues would surely have been about as common as eclipses had not science fortunately made such miraculous advances. Nor would our provincial capitals have found themselves much better off than the metropolis in this respect; and yet, in this connection, we should bear in mind two facts: first, that China is, in most respects, two centuries behind Europe; and secondly, that several of its cities contain a million or more inhabitants, while those holding between one hundred thousand and a million are reckoned by the score. Sanitation, or its Chinese equivalent, is a word unknown in a practical sense, the arrangements for removing refuse being simply an offence to English civilisation. Yet, despite this drawback and a multitude of others, the death-rate in Canton, Tientsin, Ningpo, Foochow, and other great centres in closer contact with the west, is comparatively light. What is the reasonable construction to put upon this undeniable fact? Is it not that some real virtue is to be found in most of the local medicines, of which, in the course of a lifetime, the natives swallow such a surprising quantity? The absence of oxygen in a common Chinese lodging-house alone seems sufficient to extinguish the flickering spark of life, while the mode of sleeping is enough to breed a dozen new pestilences. No European, however strong his stomach, could exist a twelvemonth, or even a week, under the distressing conditions which are the common lot of poor "Ah Sing." He would simply asphyxiate and die; yet somehow the natives seem to exist. To call their existence life would be somewhat hyperbolic, seeing they are constantly ailing; nevertheless, the drugs perpetually swallowed counteract, to a large extent, the evil effects of their many objectionable habits.

In concluding this series of papers, it may be in place to refer to a few matters that have hitherto been overlooked, or else have met with scant notice. We have already mentioned China root as among their favourite drugs. Of this plant (the *Smilax China*) such enormous quantities are consumed that it invariably obtains separate notice in the Trade Returns. It is put to much the same purposes that sarsaparilla is with us, and apparently answers as well, though experience certainly goes to show that the *smilax sarsaparilla* of Jamaica is the superior herb where European ailments are concerned. Fuling medicine is also largely used by the Cantonese; but here, again, we must admit to partial ignorance of its character and uses.

In the matter of oils the Celestials are exceptionally great. From sandal wood, cinnamon, red pepper, juniper seeds, aniseed, cassia, and cassia leaves, and many other spices, they express essential oils employed medicinally among other purposes. Even the oils extracted from tea and flower seeds are made to serve some curative purpose or another. In brief, scarce one vegetable or animal substance exists that has not, in the course of ages, been devoted to the service of *Æsculapius*—that does not minister to the necessities of China's millions.

For some occult reason—fortunately, or unfortunately, shall we say?—science has hitherto paid little attention to this interesting study. Few investigations have been made into the qualities of the thousand and one drugs that kill or cure one-quarter of the human family; and those few, we fear, were more the outcome of a desire to expose than of anything else: certainly they were not inspired always by the highest of motives, nor from a desire to add fresh items to the already over-lengthy list in the British *Materia Medica*. The long and short of the matter is that the nineteenth century, which prides itself upon its enlightenment and knowledge, remains in comparative ignorance regarding

the whole subject of Chinese therapeutics. This vast, this most fertile, field for research is as yet but partially explored. Perhaps one drug in ten finds a place in our wholesale druggists' lists; scarcely more, even if we include the several animal products with which the eastern and western worlds are equally familiar. Is this because the medicines themselves are worthless, or because they have been insufficiently tested, if tested at all? The writer's opinion leans to the latter hypothesis.

Clinical Records.

INTRA-ABDOMINAL FIBROUS TUMOUR— CÆSAREAN OPERATION—RECOVERY.

Under the care of DR. CATALIOTTI.

IN October, 1879, the maid servant of the Princess Giardinelli came under notice as having a large intra-abdominal tumour which was causing her great pain. She was on the eve of marriage when Dr. Cataliotti examined her, and he was chiefly consulted as to whether she could enter into wedlock without endangering life.

Her antecedents proved that in youth she had always been healthy, with regular menstruations. She had been at a convent where, at the end of the twelfth year of her stay, she lifted a heavy kettle, when she felt a pain in the abdomen. About a month later, at the time of menstruation, she spat blood and had violent hysterical attacks. Having left the convent, she accepted a situation as maid to the Princess, where she was seized with repeated vomiting during menstruation; it was not checked by any remedy, but stopped suddenly after the two first days. At the same time a tumefaction appeared on the lower part of abdomen, of which the origin was uncertain.

This much being known, the abdomen was examined, although certain indispensable observations could not be made, patient being a virgin. The tumour occupied chiefly the middle of the abdomen, extending beyond the umbilicus, had its chief dimension towards the right with a large lobiliform extension towards the hepatic region, and descended deeply into the cavity of the left iliac region. This tumour, most irregular in shape, hard in some places, soft in others, was but slightly movable and sensitive when touched. The patient being in the knee-breast position, the tumour was found adherent in its dorsal parts. The general state of health had suffered materially through continued illness, and the consequent abstinence from nourishment. The diagnosis arrived at was that it was a case of an inter-peritoneal fibrous tumour, most likely uterine.

In spite of the representations and warnings of the medical attendant the patient was married on the 9th February, 1880, being already in her fortieth year. After one catamenia she became pregnant. The pain was not long in reappearing, and after three months became intolerable. Called in to alleviate it, Dr. Cataliotti was unable to assist her, and the pains increased to such an extent that in the fifth month the poor woman was unable to sit or lie, and only found some relief in constant walking. Overcome by fatigue, she rested against the wall or in the corners of the room. She complained of continual shooting pains in the abdomen, and this lasted until the operation, when she repeated despairingly, "Cut me to pieces."

In the seventh month Dr. Cataliotti was again requested to procure premature confinement. The condition in which the vagina was at that time rendered this difficult. Introducing his finger into the vulva he found at the right a large tumour, immovable, and of excessive hardness, apparently emanating from the corresponding ischium. The tumour gave the vagina a conical shape; the neck of the uterus was curved on itself, and seemed to have no share in gestation. Then, as far as possible, he tried to introduce the point of his forefinger in order to reach the head of the foetus, but the patient moved so much that this was not possible. At any rate, the vagina was so contracted as to render the passage of the head of the foetus impossible, and likewise preventing the introduction of any instruments or the hand. After consultation it was agreed to attempt Cæsaean section. Two days later contractions of the uterus set in, with unbearable pain, especially in

the epigastrium, the thorax, and more especially in the shoulders. On the 28th October, the patient having been suffering for hours, Dr. Cataliotti, assisted by several other medical men, then proceeded to perform the operation. At half-past one the patient was placed on the table. She was resigned and seemed even impatient at the delay. Chloroform being administered, an incision of about five inches in the linea alba between the umbilicus and the pubes was made. When opened, a jet of serum escaped, indicating dropsy, which in itself compromised the success of the operation. This exceptional fact will be interesting from a pathological as also from a therapeutic point of view. The operation was interrupted by the abundant flow of the peritoneal effusion, and the uterus offered exceptional resistance, being entirely covered with varicose vessels. The amniotic fluid was of a limpid colour, and the foetus extracted in good condition. The umbilical cord was cut and the placenta taken out without any adhesion. This done, everything was cleared and put into order. The carbolic acid spray continued, and as the patient showed signs of coming to, the chloroform was again administered.

The operator then introduced his hand into the abdomen in order to ascertain the position of the tumour and its adhesion. The tumour formed an integral part of the uterus, its walls had entirely disappeared, and had been replaced by the neoplasm. Near the incision a mass of substance was found reaching the hepatic region. The assisting medical men having confirmed these observations, the mass was easily removed, excepting near the liver, where it was hardened by the pressure, and more adherent. Having freed it, the operator enlarged the primary incision in the direction of the umbilicus three inches to the left. He then lifted out the tumour with the whole of the uterus and adhesions. This part of the operation was extremely successful. The remaining part of the neck of the uterus being drawn out as far as possible, was next tied with a strong piece of wire fixed with a knot. Another ligature was also made half an inch lower with a piece of catgut in order to secure the former. The operator had to carefully avoid coming into contact with the bladder or the rectum, which were now in direct contact with the remaining part of the neck of the uterus; a small sharpened metallic sound between the two ligatures fixed the uterine parts outside the abdominal wall.

The operation had lasted about an hour in all. The patient was then removed to a room where a warm moist temperature had been established, and a few spoonfuls of curacao were administered to her.

During the first three days subsequently there were several slight attacks of retching accompanied by heartburn and tympanites. The patient complained of a dull pain in the abdomen, the temperature rose to a maximum of 39° C. and the tongue was dry. These symptoms indicated intestinal disturbance, more mechanical than vital; but applications of ice, lukewarm injections and hypodermic injections of morphia, and a few drops of tinct. opii, afforded relief.

After two consecutive evacuations the patient had good nights till the third day. On the fourth day the bandages were removed, when the wound was found to be nearly healed, except where the pedicle emerged and where the wound was still open, the pedicle being mortified by the strangulation through the ligature. The open wound was in good condition, and reparation continued with wonderful rapidity. The fifth day the urine flowed spontaneously without the aid of a catheter. The abdomen had gone down, and the patient felt sufficiently well to ask insistently for more solid food, and was given a little broth. On the seventh day the piece of wire fell off, and only the catgut remained. On the side of the pedicle there was putrid matter in rather large quantity of a greenish colour, which required two applications a day. The rapid gain of strength alleviated the fears of purulent dropsy. On several occasions opium and bismuth were given to stop excessive evacuations. The pedicle having fallen off the discharge of pus diminished. The patient slept quietly, and the temperature relaxed to 38° C. The moral condition was excellent, the appetite considerable; the wound granulated visibly, but did not yet make any rapid progress towards cure. The suture was still maintained for several days, and there was no great resistance in the tissues. The general condition had evidently suffered severely, as well from the pain caused by the operation as by the diet which had necessarily to be observed during the last two months of pregnancy. On the fifteenth day the suture was entirely removed, but another stitch at the lower

part of the wound was necessitated on account of the diseased state of the edges. On the eighteenth day, the weather having suddenly changed, the patient had an attack of rheumatic pleurodynia, which defied all medical remedies. The new stitch in the wound gave way in consequence of the tenderness of the tissues, and the wound had, therefore, to be treated by cauterisation. To keep the borders of the wound together a dry suture was made with collodion, which, however, was not successful. The iliac prominences rendered the use of diachylon impossible. Bands of court plaster were, therefore, placed on the wound, and fixed with small pieces of thread over the thighs, and fixed with ordinary gum, which proved most successful. So far the patient had been progressing favourably, and could have even risen had not the state of the tissues prevented. She ate and slept well, when suddenly a dry colic set in, accompanied by retching of a bilious green substance. Violent pains in the region of the spine with absolute constipation, such as even to prevent the emanation of gases, depressed pulse, dry tongue, intermittent sobbing, and depressed looks were the symptoms which caused fears of a fatal issue. All the most radical remedies were at once applied to avert the danger. Drs. Poggi and Urso again assisted Dr. Cataliotti, and they succeeded in relieving the patient. Irritant injections produced copious foetid discharges, which proved the intestinal obstruction was caused by the reduced peristaltic movement during so long a period through pressure of the tumour. The slow digestion and the heavy food to which the patient was unaccustomed probably caused these symptoms. An error of diet must have been committed, and therefore two confidential nurses were put to watch her until she was quite restored.

Her voracious appetite was such as to necessitate constant restraint, but, on the other hand, the nourishment she took rapidly restored her strength. The dry suture sustaining the wound, the same healed very slowly. It was constantly necessary to touch it with nitrate of silver. The funnel-shaped aperture gradually became smooth, and the scar was completed towards the end of the third month. Lastly, to protect the walls of the abdomen against any strain which might occur, and to guard against any accident which might arise in case the wound were not perfectly healed, the patient was bandaged with flannel.

Dr. Cataliotti expresses an opinion that this case, with its complications, presents some entirely new features, and he lays special stress on the occurrence of acid dropsy which was specially noticeable by the undulating movements of the abdomen, which was filled with the water from the amnion. The diagnosis of this was most difficult. It was confirmed by the motion of the foetus and by the fluctuation of the liquid which was concentrated, and the abdomen did not present the form usual in cases of common dropsy, because it had been completely deformed by the pregnancy, which one might almost say was within the tumour. It was not possible at the first examination to fix the exact position of the uterus, because the left lobule of the tumour descending into the lower part of the iliac cavity had displaced the corresponding wall of the vagina, rendering the neck of the uterus tortuous and not attainable by surgical means. A long and deep furrow divided the tumour of the uterus, and all the medical men were agreed that this organ had been displaced by the settling and slow development of the neoplasm, which was exceptionally hard. The uterus could not be easily distinguished before the operation, because, during pregnancy, the foetus formed the chief part of the tumour, and the furrow divided the tumour and foetus, the large lobule adhering to the concave part of the liver. The foetus, the tumour, and the uterus forming but one rendered accurate diagnosis impossible. Pathological anatomists say that when the uterus contains a new growth the complete development of the foetus becomes impossible. Dr. Cataliotti quotes two other cases of some interest; in one case a living child was born, although a tumour existed in the womb.

The patient above referred to returned to work as maid to the Princess Giardinelli, and was evidently entirely restored. A subsequent examination per vaginam showed that the organs had resumed their normal positions.

Medico-Military Items.

A CABINET MINISTER'S LEISURE.

THERE are few things more indefinite than a Cabinet Minister's leisure, and the reply to the appeal of a body of public servants that the subject of their remonstrance shall receive attention when that particular period has arrived is equivalent to classing its fulfilment in point of time with the lying down of the lion with the lamb. A year and a-half ago, when the sad list of killed, wounded, and sick among the medical officers who had served in the Cape, the Zulu, the Afghan, and the Boer wars had reached a serious total, it was brought by Mr. Findlater to the notice of Mr. Childers, in the House of Commons, that the Army Medical Department, notwithstanding their full participation in all the risks of war, were, by the introduction of the word "combatant" into certain recent warrants, excluded from the benefits conferred upon all other commissioned ranks of the army whose duties led them to be present upon the field of battle. To this the Secretary of State replied with more sophistry than justice, "I cannot undertake to lay down the broad proposition that *non-combatant* officers are to have all the advantages of combatant officers, unless the converse be also accepted; but when I have more leisure I will look into it." During the lapse of eighteen months that expected leisure has not arrived.

In the concluding action of our last war on the fatal Majuba Hill, out of five officers killed, two were medical officers.

In the opening fight of the present Egyptian campaign at Kassassin Loch the only officer killed was a surgeon-major. Surely it cannot need much leisure to enable Mr. Childers to arrive at the conclusion that medical officers, though not receiving the advantages of combatant officers, share to the full their disadvantages, and it will scarcely require much time on the part of an unbiassed observer to perceive that nothing but the rooted jealousy of "those boulders of prejudice and superstition" compels medical officers to continue to be killed on the field of battle as *non-combatants*.

CERTAIN ITEMS OF EQUIPMENT OF OUR TROOPS IN EGYPT.

ACCORDING to a published list of equipment and supplies issued for the use of the army now engaged in Egypt, every requirement, both in a sanitary and medical point of view, appears to have been provided for on a most liberal, if not actually lavish scale. For the protection of the troops when encamped, double tents have been issued to them in the proportion of one to ten men, in place of the ordinary single tents. The helmets of the men are covered with brown cloth. Not only are their eyes protected by "goggles," but the eyes of the cavalry horses are so also, by "fringes." Each man has a blanket of grey warm material. Camp kettles, for cooking, are supplied in the proportion of one to every five men. Each battalion has accompanying it two water carts. Pocket filters are issued in the proportion of fifteen to every hundred men. Arrangements on an elaborate scale are also made to ensure as far as practicable a supply of drinkable water. Each man has on his person a small quantity of bandages, calico and lint. No mention, however, occurs of a card of identity, and the experience subsequent to the skirmish at Kassassin shows how desirable such a means of recognising some of those who had fallen would have been on that occasion.

DR. JOHN MACMUNN, has left a sum of £200 to the Royal Medical Benevolent Fund Society of Ireland, and £1,000 divided among several Irish medical charities.

"SANITARY" INSTRUCTIONS FOR OUR TROOPS IN EGYPT.

It was to be expected that the authorities at the War Office would issue a code of instructions with a view to protect the health of the British troops now serving in Egypt. Considering the great advances in the science of sanitation said to have taken place of late years, and also the very elaborate details with which that "science" has come to be surrounded, if not *mystified*, the terms of the "instructions" in question have been looked for with some degree of anxiety.

The code in question includes the following instructions—viz., not to encamp upon ground recently flooded, nor upon ground recently occupied; camps to face the North; the vicinity of burial places to be avoided; to avoid drinking turbid water—it should be allowed to subside, or a little alum added to it, or filtered or boiled, or have tea infused in it. In the event of cholera or "typhoid" fever prevailing, the water to be boiled. As to meat, that containing parasites should be rejected; all should be inspected; cooking to be thorough. The use of fruit and vegetables to be encouraged. Tea, coffee, gruel, and lime-juice are recommended; the use of stimulants discouraged. The men to have a cup of coffee in the early morning. After exertion they are to allow themselves to cool before they undress. That "a sanitary committee" be appointed, and so on.

With every desire to write deferentially regarding this code, is it not really the case that among the instructions now abstracted from it there are several that no man of ordinary sense would ever think of contravening, even had they never been written? There are others that cannot be utilised under the exigencies of active service against an enemy, and there are some that would be of no earthly use were they put in force to-morrow. Is it not the case that in drawing up codes sanitary, or as regards other matters for the guidance of the British soldier, the terms of such codes have reference to what, according to the estimate of their writer, the British soldier ought to be, rather than to what he is?

RATIONS FOR THE TROOPS IN EGYPT.

It appears that the scale adopted for the supplies of our troops in Egypt is that of a strength of 25,000 men for two months. There is a contract for meat, of which a considerable quantity has already arrived at Ismailia. Preserved meat sufficient for 25 days' consumption, and biscuit sufficient for 30 days have also been received at the same place. Besides large quantities of *erbswurst*, the stores are well supplied with lime-juice and preserved vegetables. Spirits, wines, and tobacco also figure largely. And then there are "groceries," "comforts," disinfectants, and so on, almost in any quantity.

THE EMPLOYMENT OF RETIRED DEPARTMENTAL OFFICERS.

AMONG the Army circulars for the current month one gives power to the Secretary of State for War to employ retired departmental officers under such conditions as he may from time to time determine. When employed, such officers are to receive a consolidated salary, which, however, is not to exceed the amount of their retired pay by more than £150 a year. No retired officer shall, however, be liable for employment after attaining the age of 65. On attaining that age, and on ceasing to hold such appointment, they shall revert to the retired list, with the rate of retired pay of which they

were in receipt when so appointed. Retired officers, while holding such appointments, shall cease to draw their retired pay, and shall receive a consolidated salary, to be determined by our Secretary of State, but which shall not in any case exceed the amount of retired pay by more than £150 a year, and shall include all allowances, except forage, when specially authorised.

Whether the terms declared in the above Warrant are, or are not, sufficient to induce retired officers to resume the cares and responsibilities of active duty remains to be seen. The omission in the published statement of all mention of "house rent" and "servants' allowance" appears ominous. But perhaps the omission is accidental. At any rate, as in the great majority of cases retired officers have taken leases of houses, they will no doubt "consider" the terms above held out to them.

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.
 Small Announcements of Practices, Assistances, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRISTOL, post free in advance, 5s. dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 13, 1882.

LAST WEEK'S PROSECUTIONS.

DURING the past week no less than three inquiries have been held into the circumstances surrounding deaths which had been certified in a way to demand investigation. Two of these cases will form subject for further proceedings, but in the third penalties of £10 each were inflicted on a registered medical practitioner and his unqualified assistant. The offence committed consisted in the signing of a death certificate by one defendant, W. H. Dry, M.R.C.S., whereas he had not seen the patient named in it; and in issuing this same certificate by the second defendant, an assistant named Upfield. The

summonses were taken out at the instigation of the Medical Alliance Association, under the Registration of Births and Deaths Act, 1874, and charged Upfield with having given the father of a child he had attended, in the capacity of a medical man, a certificate stating that the child had died of scarlatina, the signature to the certificate being "W. H. Dry, M.R.C.S., L.S.A.," whereas Upfield had been the sole attendant on the child up to the time it died. The result of the hearing was that named above, each defendant being fined in the full penalty.

This case possesses very great importance, and we are glad to be able to congratulate the magistrate, Mr. Bushby, on so clearly perceiving the practical necessity of dealing severely with such offenders. It probably did not assist the latter much to urge against a conviction that the Medical Alliance was actuated by spite, because Mr. Dry was not a member of the Alliance. The contention was, on the face of it, eminently feeble; for we assume that Mr. Dry, being an employer of unqualified assistants, could not, even had he desired to do so, have joined the Association as a member. We confess to knowing little of the Alliance, except to admire it for its prompt and commendable action in several instances; but if it is so constituted that its ranks can by any chance remain open to persons who outrage the profession of medicine by employing unqualified men to impose on the credulous and unsuspecting poor, then it is certainly high time the Society should be remodelled. For the present, however, we shall continue to regard the assertions made by Mr. Dry and his assistant as of an impossible kind.

This case brings out also very clearly a point we have so often insisted on, that the poor who flock to dispensaries are gulled into the belief that they are receiving duly qualified services; and paying sixpence or a shilling a week, as it may be, for advice given by registered medical men. How grossly they are imposed upon such examples prove; and it is with much satisfaction that we note the increasing frequency with which exposures of the fraud are being made. Of the intention to deceive, moreover, it is no longer possible to have a doubt; for when death occurs, as it frequently must, the *modus operandi* of providing the necessary certificate is a clear indication of the deliberate swindling which goes on in dispensaries of the kind Mr. Dry has been conducting. It is no excuse for the employer of unqualified labour to urge that his assistant has been his pupil. He must know that each time he signs a death certificate in a case of which that assistant has had charge, he is committing an act of perjury, inasmuch as he distinctly puts his name to the declaration—"I attended," &c., &c. But he also knows that an unqualified man cannot legally act as a surgeon in any capacity, else why should anyone incur the cost and trouble of qualification? So that it is an act of conscious fraud for a duly qualified practitioner to send one who is not ex-qualified on the errand to which he has himself been called in his capacity as a qualified medical man.

This point is one on which we must again and again insist, for it is one which most affects the cases that are occurring now with such frequency as to be both

alarming and encouraging—alarming, as showing the extent to which evil obtains; encouraging, as showing the exertions made to oppose it. It is raised, too in connection with the second of the three cases referred to above: likewise a dispensary scandal. This inquiry was held into the circumstances attending the death of a coal porter, who was attended for some time preceding death by an unqualified assistant named Power, who had charge of two dispensaries in Islington, and who "had walked some of the hospitals in America." On the death of the coal porter, who was seen when in a dying condition by a qualified practitioner, the latter arrived at a very different diagnosis of the disease from that given by Power, whose verdict was, alcoholism. Post-mortem examination revealed extensive pneumonia; and these facts being made known to the jury, they speedily returned a verdict of manslaughter against Power. The coroner, Dr. Danford Thomas, in addressing the jurymen on the conclusion of the evidence, expressed a fear that very many London dispensaries are superintended by unqualified men; and we are of the same opinion. He likewise remarked on the injustice done to the poor, who are robbed of fees under the pretence that they are being paid for valuable medical attendance; and though, of course, he did not comment in such terms at the time on this case, we assume that Dr. Thomas would agree that no more typical illustration than that afforded by this particular instance has recently been given of the way in which money is obtained by dispensary speculators from the unfortunate dupes on whose credulity they trade.

The third case last week was investigated at the Westminster Police Court, where a certified midwife was remanded on a charge of being suspected of causing the death of a woman, by administering to her a poisonous drug for purposes of abortion. The prisoner is under remand, and will be again brought up to-day (Wednesday) in connection with the charge, which, however, is somewhat different in nature from the others we have dealt with. It has, also, less direct importance for the profession; and if substantiated, it will only serve as an indication of the fact, scarcely doubted by anyone probably, that the precautions taken to ensure that none but worthy candidates for midwifery certificates shall receive them, are not proof against the admission of an occasional black sheep. We may regret the circumstance, but cannot easily, at present, avoid its possible repetition.

CERTAIN PHASES OF THE OPIUM QUESTION.

As a matter of public health, the opium question must always possess an interest, and in these remarks our references are drawn from official and other documents of very matter-of-fact nature, in relation to the use of this drug in different parts of the globe. It appears for example that in 1871 there were in the city of Kiu Kiang on the Po-Yang lake, 197 opium smokers. Of these some had smoked the drug almost thirty years, others during various periods down to ten years, but apparently none for less than that period; hence it was probably only those who had persisted during a decade in the habit who

were looked upon as experienced smokers. It is especially observed, however, that the whole of these one hundred and ninety-seven persons had, during the year named, applied for medicine to break them of the habit. And yet it would appear that the use of opium has its advantages. Thus, not only has it the reputation of operating as a prophylactic against malarial fevers, but that several persons who had abandoned the practice became attacked by ague with or without diarrhoea; also that two opium smokers having been similarly attacked, the circumstance was looked upon as altogether exceptional. At Peking, in the same year, opium was described as being "of all our luxuries, the surest destroyer of health, prosperity, position, and life." In the reports for 1877-78 we learn that in Wenchou poisoning by opium is common during certain seasons of the year; also that during the prevalence of cholera, opium smokers, when attacked, almost always succumbed to the disease. It is observed also that the effects of opium, when consumed in smoking, differ from those of the same drug when eaten, or when injected hypodermically.

According to official reports, the use of opium is very frequent among the native criminal classes in Burmah. Of the native prisoners in jail at Rangoon in 1881, twenty three per cent. were addicted to opium smoking. Of this number, twenty per cent. had suffered in health or constitution from the practice. It is observed, however, that the sudden deprivation of the drug to which they were subjected in prison produced no ill effect upon them—a circumstance which is somewhat opposed to the usually entertained belief as to the difficulties and dangers which attend sudden cessation of the habit. Thus, the results of most recent observations fully confirm the statements made by a late Commissioner of that province with regard to the demoralisation, misery, and ruin produced among the Burmese by opium smoking. In fact, there is reason to believe that evil results from the use of opium are even more pronounced among them than in China itself. The great and rapid increase of opium smoking among the criminal classes in Burmah has become a subject of serious importance. Its extent is shown by the fact above recorded, that whereas in 1880 thirteen per cent. of the prisoners in Rangoon jail were opium smokers, the proportion in 1881 had increased to twenty-three per cent.

A second report of the Customs Department in China gives some very interesting particulars regarding the use of opium in that Empire. From calculations therein detailed, it appears that opium smokers in proportion to the population number about three and a third per thousand; that the average smoker expends daily in the purchase of opium a sum equivalent to tenpence three farthings sterling, provided he indulges in the foreign drug, but only equal to fivepence farthing if he is contented with that grown in the country itself. As to the total amount in money spent by China upon this luxury, including that produced at home and imported from abroad, it is estimated to be no less than twenty-five millions of pounds sterling per annum. Chinese who have studied the question are opposed to a traffic which more or less harms smokers now numbering over two millions, and annually

increasing. At the same time, they admit that opium provides a large revenue; that the expenditure for opium, and liability to the incidence of opium taxation, touch an infinitesimally small percentage of the population; and that neither the finances of the State, nor the wealth of its people, nor the growth of its population can be specially damaged by a luxury which only draws from fivepence to elevenpence a-piece a day from the pockets of those who indulge in it—namely, two-thirds of one per cent. of the population. They admit all this, but they do not find in either the revenue produced, or the statistical demonstration of its percentage innocuousness, any sufficient reason for welcoming the growth of the trade, or for desisting from the attempt to check the consumption of opium. In reference to these remarks, however, it is asserted that in 1854 the estimated number of persons in China addicted to opium smoking was three millions; that in 1871 there were supposed to be three or four millions of smokers; and that more recently the numbers have increased to six millions of smokers; moreover, that "there is a deeply-rooted conviction in the Chinese mind that opium does unutterable harm to the country." In America the habit of opium smoking, introduced in 1868, has already spread to an alarming extent, not only among Chinese, but also among Europeans.

The first mention of the use of opium by the Chinese occurs in their Herbal, (a) written over two hundred years ago. Under the name of *opien*, the drug was then manufactured from the native grown poppy; but there appears also to have existed a foreign trade with the drug, the Portuguese alone importing it, and continuing to import it up to the year 1767. With the fall of the Mogul Empire, the monopoly of the growth of opium in British India descended on the conquerors. In 1773 the English made their first venture to introduce it to the China market. In 1796-9 the Chinese Government prohibited its importation, and forbade its consumption, under severe penalties, but without lessening in any way the quantity entering the country, as smuggling and bribery from that time forward took the place of open trade. In 1839 the seizure by the Chinese authorities of the opium on board British ships led to the "opium war," which continued during the subsequent three years. From the date of its conclusion till 1858, smuggling continued as before; but in that year, in accordance with Treaty, opium was admitted at certain ports, subject to a duty. In 1860, after a second war, the Chinese legalised the trade—whether under compulsion, or of their own good will, is a question apparently answered variously, according to individual predilection. In 1869 an appeal against the traffic was made to the English Government, who, it is asserted, "passed it by unnoticed;" and so, "from the beginning of this century to the present hour, opium has been cultivated in India expressly for the China market." Then follows a series of tables, for the purpose of showing the steady increase from this source to the revenue of India, from £838,450 in 1834-5 to £6,521,456 in 1877-8, the total net revenue of that Dependency being in the first-named period £14,392,309, and in the second £38,656,484. According to the Budget statement recently made in the

(a) "Opium Smoking," by H. H. Kane, M.D. New York. 1882.

House of Commons, the estimated revenue from opium in India for 1881-2 was £7,250,000.

The opium question, in as far as it bears upon the finances of India, has been discussed somewhat after this manner:—To sever the direct connection of the Government of India with the trade would be—so it is surmised—to stimulate instead of checking the consumption of the drug, not only by the Chinese, but by the natives of India; while to suppress the trade would be to entail bankruptcy on the country for the sake of an illusory advantage. The Chinese, if unable to obtain the drug from India, would procure it from somewhere else, and home production of it would greatly increase. In addition to this, the abolition of the opium traffic would entail upon the Indian Government a loss of five millions sterling per annum, and besides would for a time at least, so depreciate exchange as to derange the commercial relations of the country. As matters stand, the duty on salt in India has been reduced on the strength of the opium surplus in the last Budget. Thus our own subjects have directly benefited. Hopes have also been expressed that the charges on salt may be still further reduced from a continuance of the same surplus, although the uncertainty of the latter is well known and recognised. In reference to the revenue which India derives from the opium trade, the remark has been made that that revenue is as justifiable as the Excise duties of the United Kingdom, and that few administrators would seek altogether to abandon the latter as an item of public revenue; and, further, that sumptuary laws have never succeeded. In reference to the views thus obtained from official utterances, however, the circumstance is noteworthy that according to recent accounts from India the export duty on Malwah opium has been reduced by Rs. 50 per chest to enable that drug to compete with the opium grown in Persia and China. The circumstance has an important significance. It shows that the revenue from this source must be fluctuating and uncertain; that, therefore, upon fiscal grounds alone the cultivation of the poppy must less and less be depended upon; that other industries must more and more take its place.

From these references, therefore, several points are prominently brought out, namely, that confirmed opium smokers, as a very general rule, are themselves very desirous to abandon the evil habit. That the drug (in moderation) is considered to be a prophylactic against malarial fever, although its operation as such is not invariable and constant. The evil effects of opium in regard to health, morals, and prosperity are acknowledged and represented by the Chinese themselves. The effects differ according to the manner in which the drug is used. In Burmah, a large and rapidly increasing proportion of the convicts are addicted to the use of opium. There is reason to that believe in China the actual number of persons addicted to opium smoking far exceeds the official estimate, also that the vice is rapidly extending in that empire. Opium smoking only introduced into America so recently as 1868, has there already increased greatly. Although the opium traffic with China existed before it was taken up by the British, it has greatly increased under them, and at the present time supplies a very material item in the revenues of India. Importation of the drug into China prohibited by the Chinese Government was subsequently effected by

illicit means; it led to two successive wars, and according to some accounts is now legalised by the Chinese against their own convictions. The drug is cultivated in British India, especially for the Chinese market. It is argued that to sever the existing communication of the Government of India with that trade would tend to increase the supply and demand for the drug. It would further involve a serious pecuniary loss to the Government, and also derange financial transactions with England; it would moreover necessitate increased taxation on salt in India. Finally, the revenue which India derives from the opium traffic is considered to be as justifiable as is that which England derives from her excise duties.

Therefore, the whole gist of the matter is that the opium traffic is confessed to be most pernicious in its results alike to health and morals of a large proportion of persons in China, Burmah, and America, nevertheless; but as it supplies India with a very large money revenue, on the same principle that excise duties add materially to the revenues of the United Kingdom, the continuance of that traffic on its present footing is unavoidable. But inasmuch as the extent to which opium is now produced elsewhere than in India has already to a material degree affected the revenues from this source in that country, the fluctuations and uncertainties from the same cause promise in the future to increase from year to year.

THE MEDICAL SIDE OF THE WAR.

A SEVERE and trying climate; desert tracts, on the surface sand of which the feet of men and horses sink deeply; scanty and otherwise unwholesome water; food neither overabundant in quantity nor very palatable in quality, such are some of the items that militate against our troops now in Egypt. Of these, the greater number are inseparable from active service anywhere out of the temperate zone; others are in some respects peculiar to that country—among them, notably, the physical conditions just alluded to. With such difficulties, among others to be encountered, it was natural to anticipate the occurrence of a large amount of sickness among our forces; hence it is that the hospital establishments provided for the expedition have been upon a scale as regards *personnel* and *matériel* hitherto unknown, except perhaps those for the comparatively small force some years ago fitted out for Ashantee. With that portion of the force which has proceeded from the west there have been sent not only the means for first help to sick and wounded of individual regiments, but also for field and general hospitals to be established at suitable points; while for such men and officers as, on account of wounds or sickness, require removal from the country, hospital ships are provided for their transport to Cyprus, Gozo, Gibraltar, or England, according to circumstances. As regards the forces sent to Egypt from the east, the liberal and efficient scale upon which the Government of India on all occasions provides for sick and wounded soldiers on active service gives assurance that on the present occasion the principle has not been departed from.

Records of the campaign in which, at the beginning of the present century, our forces were engaged in Egypt, gave ample information regarding the diseases to which

our men on the present occasion are most exposed, as to the classes and description of men most liable to be attacked by them; they further contain ample directions as to the protective measures to be taken against the occurrence of endemic illness and epidemic disease, in the event of the latter occurring. But in many respects our troops are in far better hygienic circumstances than were their predecessors eighty years ago. In respect to food, clothing, protection, and general attention to personal comfort, they are looked after in a manner then not dreamt of. And what is likely to be the result upon their health of such improved conditions? Time alone can furnish a reply. As far as experience on the present occasion has taught a lesson, it is that the diseases most to be dreaded among our troops are fever and exhaustion from exposure to sun and high temperature; dysentery and diarrhoea, partly from the use of bad water, partly from alternations between day and night temperature, and exposure, such as is inseparable from duties in times of war. No doubt it is with reference to the latter diseases that, under sanction of the medical authorities on the spot an allowance of spirits has been issued to the troops; no doubt also, a "tot" of rum under the circumstances is both grateful and beneficial.

So far, our troops are free from epidemic disease in any form. It is true that from the Red Sea on the one hand, and from the direction of Western Persia on the other, danger in this respect is not altogether absent. As regards the first, quarantine imposed for a few days on ships has been removed; as regards the second, no steps whatever have been taken as yet. How far the maintenance of quarantine regulations compatible with military exigencies in time of war is a question not yet presented; neither is it necessary for the time being to consider how far that measure may be expected to prove effectual for its intended purpose. All that need now be said is that, fortunately no measures of quarantine are called for. The general state of health of the army now operating from Ismailia appears to be neither better nor worse than might naturally be expected under the particular circumstances of that portion of the expeditionary force.

According to some of the published reports from Egypt certain difficulties exist in regard to transport, food, and medicines for soldiers in the advanced positions. Such things are inseparable from a state of war, and it is altogether too much to expect or look for regularity in these or any other respect such as characterise the ordinary regimental routine of an English garrison. War cannot be carried on without "roughing," and it is only the physically strong who can, uninjured, go through the process.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Bristol 15; Cardiff 16; Derby, Plymouth 18; Norwich, London, Edinburgh 19; Portsmouth 20; Birkenhead, Nottingham 21; Bradford, Glasgow, Oldham 22; Newcastle-on-Tyne, Leeds 23; Brighton, Leicester, Bolton 24; Huddersfield, Liverpool 25; Salford 26; Dublin, Blackburn, 27; Birmingham, Wolverhampton 28; Sheffield 29; Sunderland, Manchester 30; Preston, Hull 34.

Notes on Current Topics.

Fever-spreading Arrangements.

WE have so often drawn attention to sanitary defects and other causes which contribute to the spread of infectious diseases that it might almost be imagined the number of contrivances of this description has been completely catalogued. Not a week, however, elapses without the belief which encourages such a notion being rudely shaken, and we may confidently anticipate that the ingenuity of sanitary officers will long continue to be exercised in overcoming the constant tendency to invent new means of spreading infection apparent among the more crowded populations of this country. A very striking example to this effect came to light on Friday last at an inquest held at Southwark on the body of a four years' old child, which had died from scarlet fever. The mother of the victim, with an unusually intelligent perception of the relation between cause and effect, attributed the fatal illness of her child to the evil influence of a neighbouring dust-bin, which had some time previously been removed from its original position to a spot immediately beside her own back kitchen. The smells from this undesirable addition to its surroundings rendered the back of the house entirely uninhabitable, and the unfortunate family were driven to live entirely in the front room of the establishment. The children, however, could not be so confined; it was impossible to prevent them from playing more or less closely about the intolerable nuisance near by; and the not surprising consequence was serious illness, terminating so far in the death of one of the children. It was elicited during the inquest that such occurrences may take place with considerable frequency, since the neighbourly feeling which regulates the inter-communication of the poor prevented the registration of such complaints as might have resulted in removal of so great a nuisance. It is quite clear, nevertheless, that under a system of periodical inspection of all tenements and dwellings, existence of a foul source of disease could not long remain undiscovered and unremoved. It may be urged with strict justice that considerable additions would have to be made to our present sanitary service in order to carry out regular and systematic inspections; but it has been so often of late conclusively shown that inspection of this nature can alone be trusted to for effectually remedying a vast number of fatal defects in poorer dwelling places, that it may be well to make early provisions for what will some time else be inevitable. Certainly such frightful dangers as those described before Mr. Collier ought never to be seen in any civilised community.

Sunday Recreation.—How it is Prevented.

IT is now so generally admitted that the efforts of the Sunday Society to secure for the people means of healthy and rational recreation and enjoyment by throwing open public museums, libraries, &c., &c., are calculated to advance the national progress that it is impossible not to feel surprised at the action of a presumably intelligent body of men who condemn the principles involved. Such action, however, has been taken by a society of persons engaged in attending libraries, called the Library Asso-

ciation, and which has, during the past week, been holding a series of meetings at Cambridge, under the presidency of the University Librarian.

Among the resolutions proposed was one by Mr. E. B. Nicholson, Bodleian librarian at Oxford, in favour of the general principle of opening museums, libraries, and galleries for at least part of each Sunday. We are informed that in place of discussing it, the previous question was carried "by acclamation." It is right that the circumstances under which this remarkable evidence of a sagacity was exhibited, should be remembered. The vote was the vote of men, as a rule, but little cultured, the 'Library Association' being made up almost entirely of the officers who are chosen to superintend free libraries and similar institutions in this country. But few of them would be actuated in a question of the kind under notice by any higher feeling than that of self-interest, which necessarily urges them to persistently oppose any movement, the success of which would entail additional labour on themselves. The few highly cultured members of the Association, like Mr. Nicholson, who is a distinguished Oxford graduate, naturally view the action of their fellow members with deep regret, as also must all who value the welfare of the British Nation. That interested librarians, however, can influence the success of the Sunday movement by passing any number of resolutions of the "we don't want to work" type, is absolutely impossible; but it says little for their intelligence as a body that they should so strongly oppose a proposal for extending the usefulness of their own services.

The Fever at Accrington.

THE epidemic of scarlet fever at Accrington, in spite of all precautions is spreading. One medical man alone reported no less than 20 fresh cases during last week. There were 22 deaths registered, 18 of them being children under eleven.

The Poison of Mushrooms.

A PARAGRAPH has been going the round of the press stating that Prof. Ponfick has been making experiments on the common mushroom, and has discovered that it is highly poisonous, particularly when uncooked. It may relieve the minds of some to learn that the professor's experiments were made on the *Morchella esculenta*, and not on what is generally known as the common mushroom (*Agaricus campestris*). The latter, we have often eaten uncooked, and in pretty large quantities, and are, therefore, quite in a position to place our experiments by the side of the dictum of our contemporary which made the discovery. There is hope, moreover, even for those who have eaten the *Morchella esculenta* uncooked, as the smallest quantity that invariably proved fatal was two per cent. of the body weight of the animal experimented on. This would represent in a person 150 lbs. in weight three pounds of the mushroom in question, a quantity, we need hardly say, not likely to be consumed by one person at one meal.

DR. GRIFFIN reported last week to the Westport Guardians that there were eight cases of typhus fever at present in Clare Island.

An Australian Medical Insurance Fraud.

THE Melbourne *Argus* of May 10th gives the history of a case lately tried in the colony. The principal defendants were Barker and Hicks. Barker who was a trusted servant of the Mutual Provident Society, having acted as a canvassing agent for many years, had a tent in the Exhibition grounds, in which he held forth as to the advantages of life assurance, and solicited business for his company. To him came Hicks, a broker and canvasser for the society, with the suggestion that "this gambling in lives" might be turned to profitable account. His proposition was that some person with only a short time to live should be insured as a "good life" and that arrangements should be made so that when death occurred the proceeds of the policy should go into the pockets of the conspirators. Barker agreed, and it was resolved to effect an insurance for £3,000 in the Mutual Provident Society, and another for £5,000 in the Alliance Assurance Company, making together £8,000. For the purposes of the plot, two confederates were required, viz, a medical man, who would give a false report, and a person to whom the policies might be assigned, for, of course, to make the money directly payable to Barker and Hicks would have been to excite suspicion. The medical man was found in Dr. Horton, while a person named Forsyth, who absconded before the trial, acted as assignee, and the compact was that the proceeds of the conspiracy should be equally divided amongst these four. The next thing was to select a fit subject for insurance, and the conspirators laid their hands upon a man named Weatherhead, who was completely destitute, and almost in the last stage of consumption. He was passed as a "first-class life" by Dr. Horton for the Mutual Provident Society, and another practitioner, Dr. Morrison, was induced, partly by a bribe and partly by a statement as to what Dr. Horton had done, to certify in a similar manner for the Alliance Company. It seems to have been an easy matter to persuade two people who had never seen Weatherhead in their lives to sign their names to the usual "friends" report. The question now was, what to do with Weatherhead, whose end was rapidly approaching. It was not considered prudent to allow him to die in Adelaide, so he was taken to Melbourne, with the intention of placing him on board a ship then about to sail for London. It was morally certain that he would expire during the voyage, and it was thought that he could be quietly buried at sea without awakening suspicion. Weatherhead, however, was too far gone to be taken on board, and he died in Melbourne. At this stage of the affair occurred an incident which requires some explanation. Hicks, (who was accepted as Queen's evidence), swore that the certificate given by Dr. Beaney set out that the cause of death was laryngeal phthisis, and that the deceased had been ill about twelve months. As Weatherhead had been insured for less than six months, this, as Hicks said, "would never do." Upon representations made by Hicks to the undertaker the words "twelve months" were altered to "three months." This was after the certificate had been filed in the Registrar general's office. How such an important alteration could have been made in this manner it is difficult to understand. The conspiracy, therefore, seemed to be in a fair

way to succeed, when the whole fabric of deception was blown to the winds by a simple act of carelessness on the part of Hicks. A tell-tale letter and telegram which Hicks had torn up and thrown on the floor, were picked up by a woman, who joined the pieces together, and read words which induced her to communicate with the Mutual Provident Society. Barker, Hicks, Forsyth, and Dr. Horton were charged with conspiring to defraud the Mutual Provident Society, and Dr. Morrison was charged with defrauding the Alliance. Forsyth absconded, and Hicks turned Queen's evidence. The case was so strong against all the defendants that they would probably have been convicted without the testimony given by Hicks in the witness-box. Indeed, if anything could have saved the prisoners, the fact that Hicks was their accuser would have done so. Barker was sentenced to two years' imprisonment for each offence, Horton to two years' imprisonment, and Morrison (who was recommended to mercy by the jury) to one year's imprisonment.

Neglect of Death Registration.

It seems to us that medical officers of public institutions in Ireland need some more stimulation to discharge their duty in respect of registration of deaths, and that, inasmuch as the official mention of their neglect of duty in the Registrar-General's report does not appear to influence them to punctuality and business habits, it is necessary that that functionary should take, as the lawyers say, "such steps as he may be advised" to enforce regularity in this matter. We are familiar with the paragraphs in the Registrar-General's reports respecting the negligence of certain officials of institutions in Dublin, and we find from the report for this week that the Registrar of Waterford No. 1 District remarks, "*apparent increase of total death-rate due to registration of 14 deaths at District Lunatic Asylum, dating from December 3rd, 1881, to the present.*" It is, we think, a very gross piece of mismanagement in any institution that the deaths therein should be held over for eight months without being reported to the proper authority, and we hope we shall not again be obliged to notice a similar occurrence at the Waterford Asylum or elsewhere.

Alleged Poisoning of a Town by Lead.

THE Keighley (Yorks) Town Council had to answer last week in the Coroner's Court on a charge of having slow-poisoned a citizen by the lead dissolved in the drinking water supplied by them to the town. The widow of the deceased deposed to his death, and that both he and she had suffered two years ago from lead poison. The pathological appearances were suspicious, but inconclusive; but the medical witness admitted that he did not find sufficient disease to cause death except from lead poisoning. Deceased visited him about two years ago, and then he was suffering from lead poisoning. At that time he advised him to discontinue using the water. A juror asked if he had come across many cases of lead poisoning. Witness said he had reported *sixty-four cases* to the local board twelve months ago. The lead was dissolved from the pipes by the action of the water. It was his opinion but for lead poisoning the deceased would have lived an average life.

Newspaper Paragraphing respecting Dublin Surgeons.

WE are reluctantly obliged to notice again the extent to which paragraphing is employed in Dublin as a means to public notoriety. It is not unreasonable that a physician or surgeon leaving his business for a prolonged absence should let his patients know that he has left home in order that they may be saved a fruitless journey to town. But there can be no necessity for the publication of this form of advertisement when a practitioner is going on a commonplace country call for the night, or from Saturday to Monday. Nor is the advertisement at all improved by the statement that the gentleman in question has been summoned by telegraph or by post-card or any of the ordinary means of communication. Two of these announcements have recently appeared—in reference to one Dublin surgeon—in the daily papers of that city, and our opinion has been challenged respecting their style and respecting the following paragraph cut from the newspaper of the locality to which the anxious public had already been informed that the gentleman had gone:—

"Dr. . . . of No. . . . Square, Dublin, Fellow and Examiner (*sic*) of the Royal College of Surgeons, the very eminent and consulting surgeon of Ireland, paid a visit to . . . yesterday, and was much pleased with what he saw of our city, particularly with our noble river, which that excellent authority considered ought to keep us free from epidemic disease. Surgeon . . . returned to Dublin this day."

The ill grammar and errors of fact of this paragraph make it obvious that it was not written by the gentleman in question; but we feel it necessary to say that such a professional puff is indecent, and certainly not calculated to maintain the reputation, honour, and dignity of any person or institution. It needs to be at once publicly and sternly repudiated. Reporters are men of business. They print these paragraphs because they think that their doing so will be agreeable to the person referred to; and they have some justification for that impression when they see every trip for a day out of town "by telegram" chronicled in the fashion columns of the papers. Those who suffer as the surgeon here referred to has done owe it to the profession that they shall at once make the public aware that they utterly repudiate such puffs, and that surgeons of respectability do not descend to such means of achieving publicity.

The Parkes Museum of Hygiene.

THE Council of the Parkes Museum have just acquired new premises in the West-end of London, near Cavendish Square, to which the contents of its present temporary home in University College will be removed as soon as the necessary alterations and additions are completed. The new building will consist of a central hall suitable for meeting and lectures, a library, and corridors, all lighted from the top, and well suited for exhibition purposes. The meetings and lectures on sanitary and other matters connected with the health of the people, which were only occasional while the museum was at University College, will henceforth form a permanent feature of the institution.

Anti-Vaccination.

RECENTLY, at the Leicester Police Court, a large number of persons were summoned for refusing to comply with the Compulsory Vaccination Acts, by not having their children vaccinated. There are several thousand unvaccinated children in the town of Leicester, and their number is increasing at a very rapid rate, although there are more prosecutions under these Acts in this place than in all the other large towns of the kingdom put together. It is urged by the anti-vaccination party that, notwithstanding this state of things, the town is perfectly free from small-pox. This immunity is, however, mainly due to the energetic action taken by the medical officer of health for stamping out the disease upon its first appearance. In the present instances most of the defendants were fined 10s. each, or seven days' imprisonment.

A New Mydriatic.

HYOSCIN, prepared by Ladenburg, and crystallisable by hydriodic acid, has proved to possess, if dropped into the eye, a remarkably rapid mydriatic effect, and surpasses, in this respect, atropia in a high degree. But the solution should be only a half per cent. one, as stronger solutions ($\frac{1}{2}$ per cent.) cause already general symptoms, as, unconsciousness, disturbances of articulation, vertigo, and dryness of the throat. It may be mentioned that this preparation seems to be well tolerated by the conjunctiva, even if kept a long time in contact with it.

The Inland Revenue Report.

THE report of the Commissioners of Inland Revenue for the past year—a report of the Principal of the Laboratory—says that the work under his superintendence has recently very largely increased, the number of samples examined last year having amounted to upwards of 26,000, or an increase of 8,000 as compared with the number mentioned in the last report. This increase is attributed principally to the beer duty and to the new regulations. Besides the analyses made in connection with the Customs, there is now a large amount of work done in the examination of samples of goods supplied under contract. The necessity for the service may be estimated by the fact that, taking the India Office as an example, out of 488 general samples submitted, 87, or 17 per cent., were reported against. Nearly one-half of the samples of wine analysed fell below the standard, and 63 per cent. of the samples of brandy, which by the terms of the contract was required to be derived solely from the fermented juice of the grape, had to be rejected, as containing variable proportions of grain spirit. The adulteration of oils, too, has been found to have lately become very general, sophistication being effected in more subtle and ingenious ways than formerly. For the Board of Trade, 86 samples of lime-juice and 550 samples of lemon-juice had been examined, with the result that 6 per cent. of the lime-juice and 16 per cent. of the lemon-juice (the latter representing more than 14,000 gallons) were rejected. Most of the rejected lemon-juice, though otherwise satisfactory, contained free pulpy matter, having been prepared early in the season, when lemons are required for making candied peel, and the squeezing is done expeditiously,

so that the juice is looked upon rather as a by-product. The pulpy matter has, however, to be got rid of by filtration before the juice is fit for use on shipboard, and as this operation is tedious, attempts are made to get juice containing pulpy matter passed, in order to avoid the inconvenience and expense of clarification.

British Prudery.

IN reproducing and commenting upon the article by Dr. S. Daniels, of St. Petersburg, on "Diseases of Sexual Organs in the Insane," in our columns under date of August 16, *La France Médicale* makes the following comment:—

"Le rédacteur de *The Medical Press* nous paraît à son tour se laisser avant tout dominer par ses instincts de pudeur britannique. Nous ne pouvons trouver aucune immoralité dans les examens faits dans l'intérêt des malades, et d'autre part nous ignorions qu'on ne pût chez les aliénés traiter toute affection autre que leur folie."

If the editor of *La France Médicale* had taken the trouble to understand what we did say his comment would have been needless. We think it quite consistent with *pudeur britannique* to treat any and all diseases our patients may suffer from; but we cannot say the same of the practice of making vaginal examinations in every case of lunacy occurring in females where there are no symptoms present pointing to possible disease of sexual organs, simply because the patient happens to be insane.

A Man of Great Brain.

ACCORDING to our excellent contemporary *Knowledge*, "The heaviest brain ever weighed in the United States was taken from the skull of James H. Madden, who died at Leadville on July 6th. The doctor who attended him during his last sickness had observed the immense frontal and lateral development of his head, and determined to weigh the brain, but his astonishment was great when it brought down the scales at sixty-two and a quarter ounces. Cuvier's brain weighed sixty-four and a-half ounces, considerably surpassing all other records; but the brains of Napoleon, Agassiz, and Webster, though phenomenally heavy, were much lighter than Madden's. It is an interesting circumstance that Madden was not a naturalist, a soldier, or a statesman, but a gambler."

THE annual death-rate last week in the large towns from the principal zymotic diseases was again below the average, if we except a few towns, such as Hull, Preston, Manchester, &c., where it was excessive, chiefly from diarrhoea, from which disease the mortality ranged last week from 0.6 and 1.0 in Huddersfield and Bristol, to 14.4 and 14.5 in Preston and Hull. The highest annual rates from whooping-cough were 2.4 in Birkenhead, and 2.5 in Blackburn; from scarlet fever, 1.3 in Nottingham and 1.4 in Sheffield and Newcastle-upon-Tyne; from measles, 2.5 in Huddersfield; and from fever, 1.3 in Leeds. The 35 deaths from diphtheria included 18 in London, 9 in Glasgow, and 2 in Birmingham. Small-pox caused 7 deaths in London, and one each in Nottingham, Manchester, Hull, and Newcastle-upon-Tyne.

The Cholera.

ACCORDING to an official despatch from Manila, 233 natives and four Europeans died there in one day last week of cholera, including the American Consul. In eighteen villages in the province of Manila there have been 368 deaths.

FURTHER news of a very terrible nature has been received here from Iceland. The population, who have already suffered severely from famine, is being decimated by an epidemic of measles.

THE University of Wurtzburg, at its third centenary *fête*, made Doctors of Medicine *honoris causâ* of MM. Ranvier and Charcot, and Surgeons of Messrs. Lister and Paget, of London. The Faculty of Philosophy also conferred the same honour on Prof. Huxley and Sir J. Lubbock.

LAST week a patient died under chloroform at the London Hospital in precisely the same way as the one reported in our last at University College Hospital. Both had gone to hospital for the purpose of undergoing an operation for cancer of the tongue, and both died whilst under the influence of the anæsthetic before operation.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follows:—Calcutta 26, Bombay 25, Madras 33; Paris 23; Geneva 30; Brussels 25; Amsterdam 18; Rotterdam 23; The Hague 21; Copenhagen 33; Stockholm 37; Christiania 28; St. Petersburg 42; Berlin 30; Hamburg 26; Dresden 26, Breslau 40, Munich 24, Vienna 22, Prague 29, Budapesth, 29, Trieste 31, Rome 22, Naples 31, Turin 22, Venice 34, New York 40, Brooklyn 32, Philadelphia 26, and Baltimore 31.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

A FRENCH SURGEON ON GLASGOW LIMBS.—In an editorial notice in *Le Progrès Médical* of the 26th ult. of Dr. William McEwen's book on Osteotomy, the author is quoted as stating that, having practised 835 osteotomies on 557 limbs, and not having lost a single case as the result of the operation, he does not consider himself as exaggerating unduly in holding antiseptic osteotomy as one of the most certain operations of surgery. It is very reasonably stated by the French writer that it would be difficult to account for this large number of operations, if regard were not had to the special circumstances of the Scotch surgeon; and M. Desmons, of Bordeaux, is quoted as throwing light on the matter in the following terms: "I considered at the onset how so much rachitis and so much *genu valgum* and *varicus* could be collected in one of the hospitals of a single city. In traversing the city I soon found an explanation of the circumstances. Every moment I encountered persons affected with bow-legs or curvatures of the thigh. It was the more easy to discover these, seeing that numbers of the people, women and children, paraded voluntarily with naked limbs and feet." We cannot help remarking that we regard this description of women and children in

Glasgow as savouring of the mental Orientalism of our Gallic neighbours. It is not at all unlikely that for the women of Glasgow Mons. Desmons may have mistaken some of Her Majesty's gallant forces often located in a suburb of the city.

BEQUEST TO THE WESTERN INFIRMARY, GLASGOW.—Mr. A. F. Stoddard, of Broadfield House, Port-Glasgow, has bequeathed the sum of £1,000 to the Western Infirmary, Glasgow, for the upkeep of beds, which sum is to be paid in five annual instalments of £200 each. The amount required for the upkeep of one bed for a year is £50. The bequest will therefore maintain four beds annually for five years. During the past year the Western Infirmary has made considerable progress financially, but as the expense of the Free-laid Wards, which afforded an addition of 200 beds to the accommodation, has fallen upon the institution this year, there is a prospect of a considerable deficit in October next.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 2nd inst., was 89, and the death-rate 18 per 1,000. There were 18 deaths under 1 year, and 21 above 60 years, of which three were above 80 years. Only one death was reported from zymotic disease. It was one of erysipelas, and occurred in the Old Town.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 2nd inst., were at the rate of 23 per 1,000 per annum, against 20 in the preceding week and 21, 23, and 16 in the corresponding periods of 1881, 1880, and 1879.

CUPAR.—DECLINE OF THE FEVER EPIDEMIC.—Dr. Wm. Whitelaw, medical officer of health, forwarded his weekly report regarding scarlet fever to Bailie Simpson on Wednesday last, in which it is stated that there is a great improvement both in the number and the type of the cases. During the last week there have been reported only four fresh cases, all of an extremely mild type. No more cases have proved fatal, and all those which have occurred during the last fortnight have been of a much milder type—an almost unfailing indication that the epidemic is dying out. With reference to the proposal to close the public day-schools, the medical officer states that since they were opened eighteen fresh cases have occurred, and of these only five had attended school. He calculated that of those at school 0·7 per cent. had taken fever, while of those outside 1·2 per cent., or nearly double, had been laid up. The conclusion drawn was irresistible that the children are safer there than roaming about the streets. There therefore seems to be no necessity for closing the schools in the meantime.

Literature.

ON OVARIAN AND UTERINE TUMOURS: THEIR DIAGNOSIS AND TREATMENT. (a)

"The book which I now issue is professedly a second edition of that of 1872, but so far as the operation of ovariectomy is concerned, it is almost new, and as regards the uterine section still more so." Such are the author's words in the preface, and they indicate the vast progress which abdominal surgery has made in the last decade, an advance due in no small degree to the zeal and ability of the author.

Passing over the first 150 pages, which are devoted mainly to the pathology of ovarian tumours and their diagnosis, we come to an interesting chapter on "The Rise and Progress of Ovariectomy," including ovariectomy in France, Belgium, Germany, &c., which is in our opinion an

(a) "On Ovarian and Uterine Tumours: their Diagnosis and Treatment." By T. Crozer Wells, F.R.C.S., &c., &c. London: Churchill.

impartial record of the history of ovariectomy, giving due prominence to the services rendered by each of the pioneers of ovariectomy from McDowell downwards.

The author's opinion on the antiseptic system are worthy of serious consideration. After Listerism has been well nigh universally adopted, we have recently seen most violent attacks made on it, so violent as to lead us to fear, in some cases at least, that personal motives have warped the judgment and biased the feelings of speakers and writers. Mr. Wells certainly can have no personal object in advocating the use of antiseptics, and when he throws the weight of his mature judgment and great experience in its favour it may well make us hesitate before we set aside at the dictum of some zealous, though we fear not judicious, opponents, a system to the value of which such a body of impartial evidence has on all sides been given. To the use of the spray Mr. Wells points out some objections which all practical surgeons are well aware of; but this is only a part of the system, and though we should be slow to omit it altogether, we agree with the author that in ovariectomy it has its disadvantages. Septicæmia is the cause of the majority of deaths after ovariectomy, and everything which can be done to lessen the chances of its occurrence should be adopted, but Listerism must not be exclusively relied on, and we are of opinion that with respect to ovariectomy its value has been to this extent overrated, that it has led to the abandonment of drainage in cases in which this should have been employed. While practising Listerism ourselves we cannot, in ovariectomy, at least rely on it as being an absolute safeguard against septicæmia.

Mr. Spencer Wells, in common with most operators, has abandoned the use of the clamp, and now returns the pedicle, when ligatured, into the abdominal cavity. He believes that Listerism has enabled this important change in practice to be adopted with safety. We think, however, that that system can hardly be credited with this improvement, and we know that Mr. Keith, of Edinburgh, who has ceased to use the spray, still practices the intra-peritoneal method with safety.

But after all, the most interesting, if not the most important, part of the work is that which treats of the "Recent Extensions of Ovariectomy." The first in order of time of these "extensions" is the so-called "Normal Ovariectomy" of Battey, "whose object was to bring on old age" or, more correctly, premature cessation of the menstrual function in women in whom that function was malperformed. On this subject Mr. Spencer Wells writes with his usual good judgment. He says: "I accept the principle, but see that the operation has a very limited application, and that the conditions justifying such an operation are exceedingly rare is evident from the fact that, since his enunciation of the principle upon which he proposed to act, Battey has only found fifteen cases in which he could see reason for carrying it into practice." When we hear, then, of a local practitioner in England performing this operation seventy or eighty times in one year we feel that the "abuse" of it, which Wells feared, has become a reality.

The chapter on "Uterine Tumours" is a very instructive one; it is but a short time ago since the removal of these by the abdominal section would have been considered entirely unjustifiable, yet Mr. Wells has himself operated on such seventy times—thirty-nine of these being cases of removal, and thirty-one of partial removal, or of exploratory incision. The mortality among these is large, but there can be no doubt but that in cases in which life is endangered the operation is justifiable.

The last chapter is "On Partial Amputation and on Complete Excision of the Uterus" the author is evidently not in favour of excision of the uterus in cases of cancer, and in this we agree with him. It is seldom the disease is recognised till it has extended to the adjacent parts, and then it is hopeless to attempt an operation; but our personal experience leads us to the conclusion that cancer attacking the fundus of the uterus is not so rare as has been supposed, and that with the improved means of making a diagnosis now at our disposal, we believe that this form of the disease will be more frequently recognised and the operation more frequently performed than it has hitherto been.

The whole work is written in a simple and clear style, abounds in clinical records of plain and unvarnished facts, and is worthy of the attentive perusal of all operating surgeons, as well as of such specialists as practise ovariectomy.

Correspondence.

RETENTION OF PLACENTA FOR FOURTEEN WEEKS AFTER ABORTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to a case of retained placenta published in your issue of August 30th, under the head of "Clinical Records," I have since received a letter, from which I send the following, with the explanation that something in my report has been supposed to reflect injuriously on the medical gentleman previously in attendance on the case. The letter says: "On March 4th I was summoned to see Mrs. G. I made an examination and found a small body protruding from the os, but as it still adhered I waited till the next day, when I introduced my finger and succeeded in detaching and removing all that the uterus seemed to contain. There were no signs of the fœtus, nor did I succeed in eliciting anything which would have led me to conclude that I had any other than a very early ovum to deal with. It was evidently Mrs. G.'s intention to mislead me from first to last, and I certainly had no reason to suppose that I had to manage a case of abortion at the 10th or 11th week."

Signed,

THE "HOMCEPATH" IN QUESTION.

I feel constrained to ask you to insert this explanation as a matter of simple justice to the "homcepath in question."

I am &c.,

J. E. BURTON.

64 Rodney Street, Liverpool.

CORONERS AND MEDICAL CERTIFICATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am obliged by your insertion of my letter, and trust you will allow me to make some further remarks upon your note and Mr. Malcolm's observations.

I have never contended for the "necessity of holding an inquest into every uncertified death." For I have shown medical certificates to be given improperly—i.e., coroners' cases; and there may easily be cases, though no surgeon has attended, which do not fall within the definition of coroners' cases.

With respect to Mr. Malcolm's statement that a number of cases were "inquired into, but no inquests held on any of them, the coroner being satisfied in each case the death occurred from natural causes," I must again deny Mr. Malcolm's right to dispense with a jury and make inquiry himself, or to do more than ascertain whether the death was violent, sudden, non-natural, or suspicious. If it was, the coroner has simply to discharge his duty, whatever anyone may privately tell him as to the likelihood of there not having been foul play.

It has been truly said that no office or institution can fall except through the fault of those responsible for managing it; and I fear our own office is in danger from this cause.

I presume the cases in which the coroner's proper duty has been omitted are such as these:—Children found dead in bed, or dying suddenly in their mothers' arms, or from burns or other so-called slight injuries; persons dying from natural disease aggravated by want, exposure, removal, surgical operations, or want of medical attendance; or from fever due to foul smells, &c.; not to speak of cases where within twelve months there was some injury developing into pneumonia, for instance.

In all these cases it is easy for a coroner, by having a private conversation with some person or persons who want to prevent an inquest, to "satisfy" himself that there is nothing wrong. But it is self-evident that the coroner's refusal to make such cases a matter of open public inquiry must encourage all who are connected with similar cases in carelessness or neglect.

A solicitor in full practice who is applauded by his council, or who is paid by salary, for not "holding unnecessary inquests" may not unnaturally pass what is clearly a coroner's case under such circumstances. I am satisfied by five and thirty years' experience, both of the public protection of obeying the law strictly, and of the public danger of neglecting it. I may add that although a criminal verdict is seldom given, the presentment by a

jury of past neglect or of due precautions for the future, published with the case itself, is productive of much good, which is lost on the coroner's "private conversation" system.—Yours faithfully,

EDWARD HERFORD,
H. M. Coroner, City of Manchester.

Obituary.

DR. IRWIN, OF MONAGHAN.

We regret having to notice this week the death of Wm. Nassau Irwin, Esq., M.D., which took place at his residence on Tuesday week. Dr. Irwin has been a resident in Monaghan for the past nineteen years. Previous to coming to Monaghan he had an extensive practice at Castleblayney, where, for over twenty years, he practised professionally. Dr. Irwin was appointed surgeon to the Monaghan Militia in 1854, which appointment he resigned about two years ago. He gave up practising when coming to Monaghan to reside in 1863. Dr. Irwin was a man of independent means, having considerable property in the counties of Leitrim and Armagh. He died in the 76th year of his age.

Notices to Correspondents.

✂ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MEDICAL PUFFING.—Our attention is called to a very gross and discreditable puff of Dr. Baptist Gamble, of Enniskillen, which appeared in the local paper last week. It appears that Dr. Gamble trephined a patient, which very insignificant surgical feat the local penny-a-liner calls an "extraordinary surgical operation." All the details of this splendid achievement are given in anatomical phraseology, as if there was something worthy of notice in this trifling performance. If Dr. Gamble is guilty of this nauseous advertisement he deserves the strongest professional censure; if not, he ought to sue the local paper for the damage done to his character by the puff, and to take care that his assistant does not in future supply reporters with details of every minor operation he performs.

MR. MAKUNA.—The communication has been put forward for publication; proof will be sent you in due course.

AUCTOR OPERIS.—We are extremely flattered by your offer, which, however, it is quite impossible that we should accept, the pressure on our space being too great to allow of publication of any but purely medical essays. The papers have been sent.

MR. CHENERY.—You will probably alter your opinion when you have obtained further experience of the use of the instrument. It is a little difficult to manipulate at first, but when once employed with facility none will compare with it for excellence of result. Prepared sheets for reception of tracings are sold by most instrument makers.

R. S. H.—The Society's meetings begin in October, and run on till the end of May. The Clinical meets twice a month—on Friday evenings. You will find no difficulty in being admitted as a visitor to one of the meetings; if you apply to the Secretary on the evening you wish to attend you will be courteously and kindly received.

DR. JONES (London).—The Membership of the Royal College of Physicians of London is accessible to you, but only after examination, and the classical part of it is a *sine quâ non*. We do not think your proposal would be entertained for a moment.

DRESSER.—If you can support your statement with facts the disgraceful proceedings shall be fully exposed in our columns. The matter, however, is one of such gravity that nothing less than absolute and unmistakable proof will suffice; and unless you can produce it to complete satisfaction, it will be useless to proceed further. We do not doubt the occurrence; indeed, we know it to have frequently been so, but we have never yet been able to fix the blame in the right quarter.

THE ODOUR OF HELIOTROPE AS A NARCOTIC.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

FIR.—Having undergone a long illness of gastric fever, avoiding narcotics in the shape of opiates, I steadily refused to yield to my medical adviser this mode of obtaining relief for feverish sleepless nights. In lieu thereof, I desired that a small bunch of heliotrope should be placed in my bedroom at night. The result was, that I slept the rest of Nature every night. For a week I had a fresh bunch sent by my gardener, and for the rest thus obtained to recoup my shattered health I attach to the odour of this plant. This may be worth knowing, as it is generally thought the odour of flowers at night is not healthy.

St. John's Wood, N.W.

Yours truly,
M.D.

MR. WOMACK.—Thanks for forwarding communication; it shall receive early attention.

IMITATIONS OF COFFEE.—In the new Customs and Inland Revenue Act of this year, the sale of imitations of coffee and of coffee-mixtures is made subject to certain conditions, one of which is that the packets are to contain an exact number of quarters of a pound, and another is that a label shall be affixed to each packet, denoting the proper names of the substances of which the mixture is composed. The penalty for infringing the Act is forfeiture of the article and a fine of £30. But it is declared that the Act is not to affect any statute relating to adulteration of food.

DR. A. R. E.—The alterations do not come into force until November; write to the Secretary of the College on the second point of inquiry, as we have no information to guide us in the matter.

DR. S. B. B.—It would be impossible to mention all, and partial lists published by contemporaries are manifestly incorrect and unfair. We do not, therefore, propose devoting space to the subject, preferring students to choose for themselves or take the advice of their teachers.

AGED IN THE SERVICE.—We cannot suggest any formality you have not already gone through; your impatience for a definite reply to your application is reasonable enough; but you must allow something for the red-tapeism inseparable from official work. We opte there can be no doubt as to your superannuation.

A MEDICAL WITNESS.—The fee allowed to a medical witness in a recent similar case was £2 2s., with 15s. for the night's hotel expenses, and travelling expenses in addition.

THE DALRYMPLE HOME FOR INEBRIATES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In his second Annual Report, the able Inspector of Inebriate Retreats strongly urges the need for the opening of the Dalrymple Home for Inebriates. Though indefatigable in their efforts, the Committee have received very limited pecuniary support. They, however, hope to be able to commence operations before the end of the year. The triumphant progress of temperance missions is daily recorded by the Press, and it is to be hoped that the unselfishness and devotion which ought to be the motive power of such a crusade will be attested by liberal financial support to the projected Dalrymple Home, as an attempt at the reformation and cure of the many habitual drunkards whose whole system has become so diseased by alcohol that absolute seclusion from temptation is essential to restore their shattered nerves and their utterly broken-down will power. Among the officers of the proposed home are the Archbishop of Canterbury, the Duke of Westminster, Lord Shaftesbury, Sir Thos. Watson, Sir Henry Thompson, Dr. Andrew Clark, and Dr. B. W. Richardson. £3,000 is still needed. Donations, also annual subscriptions, will be thankfully received by the Chairman, Canon Duckworth, Dr. Alfred Carpenter, J. P. Crodon, and your obedient servant,

NORMAN KERR, M.D.,
Hon. Sec., Dalrymple Home.

42 Grove Road, Regent's Park, N.W.

Vacancies.

Downpatrick Union, Portaferry Dispensary District.—Medical Officer. Salary, £100, and £15 as Medical Officer of Health. Election, Sept. 20th.
Glenties Union, Dungloe Dispensary District.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Sept. 20th.
Llamore Union.—Medical Officer for Workhouse and Fever Hospital. Salary, £100. Election, Oct. 4th.
Northampton General Infirmary.—Physician. Applications to be forwarded to the Secretary not later than Oct. 27th.
Radcliffe Infirmary, Oxford.—Resident Medical Officer. Salary, £150, with board and residence. Applications to be sent to the Secretary by Sept. 30th.
Winchcomb Union.—Medical Officer. Salary, £65. Applications to be sent to the Clerk not later than Sept. 22nd.

Births.

INGHAM.—September 2, at Speranza, Dalkey, the wife of Dr. Ingham, Medical Officer, Cappaduff Dispensary, co. Mayo, of a daughter.
SPENCER.—September 7, at Albion Road, London, N.E., the wife of K. R. Spencer, M.R.C.S., of a son.
SEMON.—September 9, at 59 Welbeck Street, London, W., the wife of Felix Semon, M.D., M.R.C.P., of a son.

Marriages.

MURRAY—MACKAY.—August 30, at the Cathedral, Inverness, R. D. Murray, M.B., Surgeon H.M. Bengal Army, to Mary M'Inda, eldest surviving daughter of Deputy Surgeon-General Mackay, M.D., H.M. Indian Army (retired).
SOUTHAM—HUGHES.—September 7, at the parish church, Staverton, Devon, F. A. Southam, F.R.C.S., of Manchester, to Amy, daughter of the Rev. J. B. Hughes, Rural Dean, of Totnes.

Deaths.

IRWIN.—September 5, at Tirkeenan, Monaghan, William Nassau Irwin, M.D., J.P.
KINCHELA.—August 27, at Kilkenny, Lewis Chapellier Kinchela, M.D.
MULLEN.—September 1, at Fethard, co. Wexford, Esther Jane, youngest daughter of Peter Mullen, M.D., of New Ross.
RAYNER.—September 8, at Birstall, near Leeds, Robert Rayner, M.R.C.S., aged 57.
SHAW.—August 28, killed in the engagement at Kammanna Loch, Surgeon-Major George Shaw, A.M.D.
SPENCER.—September 2, at his residence, Burton Port, co. Donegal, John Alexander Spencer, F.R.C.S.I.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 20, 1882.

STUDENTS' NUMBER.

PREFATORY.

CONTRARY to expectations expressed in the Students' Number of the *Medical Press and Circular* for 1881, we are no nearer solving the great problem of medical reform at this moment than we were twelve months ago. It is true a certain amount of energy in this direction has been shown both in the appointment of a Royal Commission and the issue of a report by that body, but it would be premature to infer from this that we have really advanced very much farther on the path of improvement. Whether the coming year is destined to witness the introduction of radical changes in the mode whereby candidates for the medical profession are admitted to qualification, it would be rash, indeed, to prophecy. If we would accept the dictum of the most capable judges of the position, we should hesitate to expect any sweeping modifications; and more especially since the remarkable document issued by the Royal Commission includes a variety of independent opinions on the main points for consideration, and the points, too, which, from an educational aspect, are of the highest importance.

Disappointingly slow, however, as the progress towards reform has been, there are not a few indications to encourage hopes of substantial amendment of existing defects at no very distant date. If it does no more than keep alive an interest in the question, and enlarge the circle of those who take intelligent cognisance of it, the agitation in favour of change cannot fail to be productive of good results; and to the extent that general sympathy is excited in the ranks of the profession in behalf of reform, will success attend the efforts of those who maintain the demand for it. As matters are at present, we have to repeat in great measure the substance of remarks made in preceding years, in pointing out to intending medical students the course they must pursue with a view to joining the profession they have chosen; while, at the same time, we offer such advice on certain details connected with the calling they embrace as may enable them to avoid mistakes which, once committed, it may be difficult to escape the consequences of.

WHO SHOULD BE MEDICAL STUDENTS.

The late Professor Rolleston was a strong advocate of the principle of selection applied to candidates for the medical profession, and Sir William Gull at the present time reflects similar opinions in the demand for an "intellectual test" in respect to medical students. Each year new burdens are laid upon these students, both by reason of the ever-increasing ground over which the field of medical study extends, and through the constant additions thereby made to the requirements of examining bodies. There is

this peculiarity also about such studies as are included in the medical curriculum, that though they may be easily mastered in the abstract by dint of sheer perseverance, yet it is only a certain class of mind that can successfully appreciate the facts that constitute the main teaching of the wards, a right understanding of which alone enables the student to become an able practitioner. Hitherto the friends of intending students have, as such, paid little attention to any questions of this nature; they have not discussed the likelihood that the destined physician or surgeon may be eminently unfitted to prosecute the labours that will fall to his lot; that his capabilities may be opposed to all chance of successful practice; and that, in his own interest, almost any profession but medicine would have suited him infinitely more advantageously, and with the performance of infinitely better and more serviceable labour to his fellows. It is to this want of perception that we are indebted for the presence in the profession of innumerable unsuccessful men. Often enough they are eminently conscientious, industrious, and well intentioned, but lacking the indispensable qualities that go to make up a skilful practitioner; they plod wearily through life, unrecompensed, and, alas! too frequently unhappy. Unfortunately, also, we cannot even now put into set form of words rules for guidance in deciding on the possession of requisite endowments in any particular case. We recognise that successful practitioners possess certain well-marked characteristics, and we can easily enough associate their success with such marks of superiority; but it would be difficult to say what traits in a youth will develop into them until we see him at work amidst cases of illness in the wards or out-patient room. Even the most ordinary practitioner requires to possess certain powers of mind in order to be of service to his patients; and it seems but wise that some consideration should be given to the question whether the would-be medical student offers evidence of exhibiting capacity for the profession he is about to enter on.

Bodily physique, too, is a detail in this connection not enough regarded. The life led by a medical man is at the best a trying one, and when his lot falls in country districts he must needs be strong in health to overcome all the difficulties of his position. Not a few young men yield early in their career to the strain put upon them by professional work, a strain they have been unable to support; and within our own personal experience cases have occurred in which most promising lives have been early sacrificed in this way. It should, therefore, be always a point for anxious determination whether the incipient student bids fair to grow into a toil supporting practi-

tioner, and mainly because this matter is rarely properly considered we have dwelt upon it in this way at the present time.

As a means of livelihood, in which light it will practically be regarded by a very large number just now, medicine offers very varying prospects. Except as general practitioners, the younger race of qualified men can hope for no immediate return on the capital expended on their education; and it must be at once admitted that the prizes of the profession do not fall to general practitioners. Specialism, however much decried, has long been, and will probably long continue to be, the high road to fortune and renown. But only the few can hope for the success represented by a successful consultant's income; the rank and file have to be content with less than this, and it is their fortune to be able to cherish the thought of medicine as the highest, the noblest, and the most deserving of all the arts.

REGISTRATION.

Having once decided to become a student of medicine, the aspirant is required to conform with certain regulations ere he can enrol his name in the registrar of such students kept by the General Council of Medical Education and Registration, the high authority in all matters pertaining to the instruction and qualification of medical men. This Council was created in 1858 with a view to maintaining order and dignity in the profession, and empowered to carry out this duty. Its mode of performing the work entrusted to it, however, has always been peculiar, and has mainly consisted in incessant additions, subtractions, multiplications, and distractions of the elementary examinations admitting to the register of students. At present every such student must, before registration, give evidence of having passed one or other of a large number of arts examinations, among them being all recognised University examinations, such as the local, the various degree examinations; the examinations of the College of Preceptors, &c., &c. Several of the qualifying bodies also hold a special preliminary, success at which equally admits to the students' register. Following registration the actual medical education commences, and may be pursued either at a hospital, medical school, or for a time under a registered medical practitioner. No time spent in the study of those subjects on which future examinations for licences, &c., to practise are held, before registration is recognised as forming part of the minimum period over which the curriculum must extend, save in the case of physics, chemistry, pharmacy, and osteology, these being subjects in which attendance on lectures prior to registration is acknowledged.

THE CURRICULUM.

The life of the medical student is minutely marked out for him by the regulations of the licensing boards, which all agree in certain principal features. Thus, no student is admitted to final examination for a licence to practice until the termination of forty-five months spent in medical study, nor until he has succeeded in passing an examination in anatomy and physiology not earlier than the end of his second winter session as a student. There is, likewise, general agreement as to the subjects of examination, these including all the principal branches of medi-

cal knowledge and practice, such as medicine, surgery, midwifery, materia medica, and therapeutics, pathology, medical jurisprudence, &c. Moreover, in order to ensure that the curriculum has been appropriately pursued, all candidates must produce evidence of having attended certain lectures and demonstrations in duly recognised schools of medicine, and of having obtained practical acquaintance with disease in the wards of general hospitals. Hence the consideration of the student's career naturally divides itself into two sections, one EDUCATION, the other QUALIFICATION. We shall consider it under each heading, giving an account first of the various educational institutions, and subsequently of those which confer licences, &c., to practise. For purposes of easy reference also the three divisions of the United Kingdom, England, Ireland, and Scotland, will be treated separately, and we shall conclude the number with a general chapter on the services, &c.

England.

I.—EDUCATION.

English medical students have the choice of a very considerable number of schools whereat to obtain the instruction necessary to fit them for examination ordeals, some being situate in the metropolis and others in the provinces. At all, very similar arrangements exist for teaching purposes, and each is in connection with a general hospital containing everything essential to the adequate study of the science and practice of medicine and surgery. As the majority of young men who enter the profession as students are so circumstanced that their removal to lodgings is necessary in order for them to be near their schools, the question of expense in this connection has to be considered in addition to the subject of fees pure and simple, and it may at once be stated that for the first two years of his student career, the pupil who can, by attending a provincial in preference to a London school, receive the advantages conferred by frequent home intercourse will do well to postpone his town experiences until after passing the first, or first two examinations, as the case may be, for the licence towards which his aim is directed. At the present time anatomy and physiology are so well taught in the majority of non-metropolitan schools, that London schools enjoy no superiority in this respect; and if the comparative tables issued each year by the Royal College of Surgeons have any value at all, they demonstrate this fact very clearly indeed.

When, however, the purely professional work is entered on, the study of medicine and surgery, it must be admitted that London hospitals present opportunities which it is impossible for country institutions to offer, and at least one year of study should be passed at a great hospital by every student before qualification, or if he can afford it, more than one. To those who aspire to hold resident appointments this course may seem unwise, because of the restrictions which confine such appointments to perpetual pupils, but in such cases arrangements are possible by which the payment of half the composition fee at some places, or even less, confers the desired privilege.

COURSE OF STUDY.

The curriculum of study is practically the same for all students at all hospital schools, and is regulated by the requirements of examining boards. The first eighteen months is mainly spent in acquiring a knowledge of anatomy and physiology, with a view to passing the first professional examination in these subjects, and at the same time the subject of chemistry is taken up. During the winter session, particularly, assiduous attendance in the dissecting-room is enforced, and will be faithfully carried out by every student who is mindful of his own interests, while during the intervening summer he should make the most of the opportunities he will be afforded of being instructed in practical physiology and histology.

The commencement of the second winter is at many hospitals taken as the period at which attendance on lectures in medicine and surgery should commence, but we would strongly advise the neglect of such subjects until the primary is successfully put away, for until that is accomplished any distraction from the pursuit of the studies connected with it cannot but assist the chances of misfortune. Such knowledge, moreover, as may possibly be gained from the lectures which could be attended during the second winter in medicine and surgery will be as satisfactorily acquired during the summer, when the primary is over, by laying a foundation by reading for systematic attendance in the succeeding winter session. In the same way we would recommend avoidance of the wards for the same reason until after the first examination is passed, or the second in the case of those bodies which require three to be gone through by candidates for qualification under them.

FEES.

The fees charged for the full course of instruction vary at different hospitals, and we cannot help a feeling of dissatisfaction at the spectacle presented by competition between those metropolitan schools which have, and those which have not, raised the amounts payable to a scale which represents a proper return for the privileges conferred. Nor can it be denied that the few hospitals which exact reduced fees suffer in comparison with those which demand larger amounts, in respect to the general character of their pupils; for, as it is unquestionable that the less desirable class of students are, as a rule, influenced by pecuniary considerations, so they flock in greater numbers to those institutions which will receive them on lower terms. In time this must affect these schools, to their detriment, by collecting at them in overpowering proportions men who are not always influenced in action by the motives which weigh most with persons of culture and refinement. Indeed, it is sincerely to be hoped that the existing differences in respect to fees may not long continue to exercise the ill-effect it is calculated to encourage. At present, the fees payable for the full curriculum vary between £90 10s. and 125 guineas in London, and in the provinces they amount to about £100 at each institution.

Scholarships and Prizes, however, offer a means by which diligent students may materially assist their resources, and even obtain assistance sufficient to all but cover their total expenses while in *statu pupillari*. At most hospitals "entrance" scholarships, equivalent to the

total "perpetual" fee, are awarded at the commencement of each winter session to new students; and in each year valuable money prizes and exhibitions worth from £5 to £50, or more, are regularly awarded after competition. Particulars relating to them will be found below.

LONDON SCHOOLS.

The Schools of Medicine in London are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named:—

ST. BARTHOLOMEW'S HOSPITAL.—*Appointments:* Four house-physicians and ten house-surgeons are appointed annually without fee; each is provided with rooms and receives a salary of £25. A resident midwifery assistant and an ophthalmic house-surgeon are appointed every six months; they are provided with rooms, and receive a salary of £25 per year. Two assistant chloroformists, salary £25 and rooms; in-patient clinical clerks; clerks and dressers to the assistant physicians.

Scholarships, etc.—There are two open scholarships in science, value £130, tenable for one year, and a Jeaffreson exhibition, value £50, tenable for two years; preliminary scientific exhibition, value £50, tenable for one year; three junior scholarships, of £50, £30, and £20 respectively; Treasurer's prize for practical anatomy; Foster prize for practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize; Hichens prize; Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships of £30 in medicine and surgery; Bentley prize, for reports of surgical cases; the Kirkes gold medal for clinical medicine.

Scale of Fees.—Fees for perpetual attendance on lectures and hospital practice, 132 guineas, payable in the following instalments: First winter, 40 guineas; first summer, 46 guineas; second winter, 46 guineas; or a single payment of 125 guineas. Fee for general subjects for students of dental surgery:—First winter, 31½ guineas; first summer, 31½ guineas; or a single payment of 63 guineas.

CHARING CROSS HOSPITAL.—*Appointments:* Medical and surgical registrars, each with a salary of £40 a year; resident medical officer, assistant medical officer, resident surgical officer, assistant surgical officer, resident obstetrical officer, assistant demonstrator, pathological assistant, clinical clerks and dressers. The resident officers are provided with rooms and commons, and the assistant officers with commons, in the hospital.

Scholarships, etc.—Two entrance scholarships of £30 and £20 respectively, tenable for one year; the Llewellyn scholarship of £25, open to all matriculated students who have completed their second year; the Golding scholarship of £15, open to matriculated students who have completed their first year; the Pereira prize of £5; the Governor's clinical gold medal. Silver and bronze medals and certificates of honour are awarded to the most deserving candidates in the various classes.

Scale of Fees.—Composition fee for matriculated students, £91 7s., payable in instalments of—First year's fees, £38 17s.; second year's fees, £36 15s.; third year's fees, £10 10s. Composition fee for the course of dental surgery, £42 2s. This school is now located in the complete and extensive new building erected for the purpose.

ST. GEORGE'S HOSPITAL.—*Appointments:* House physicians and house surgeons are elected half-yearly from among the perpetual pupils. They are entitled to hold their appointments for twelve months, and to board and reside in the hospital, free of all expense. Assistant house physician; assistant house surgeon; obstetric assistant, with a yearly salary of £100, and board and residence in the hospital; pathological curator, with a salary of £50; microscopical pathologist, with a salary of £25; medical and surgical registrars, each with a salary of £50 per annum; assistant medical registrars; assistant surgical registrars; ophthalmic registrar; ophthalmic assistant; demonstrator of anatomy, with a salary of £50; senior assistant demonstrator, with a salary of £20.

Exhibitions, etc.—The Brown exhibitions, one of £100 per annum, tenable for two years, and open to perpetual pupils possessing a registrable diploma; and one of £40 per annum, tenable for three years, and open to students in their third

year. The Brackenbury prizes: one each in medicine and surgery. The Clarke good conduct prize, the Thompson medal, the Brodie clinical prize in surgery, the Acland clinical prize in medicine, the Johnson memorial prize in anatomy, the Treasurer's prize, and three general proficiency prizes of ten guineas each.

Scale of Fees.—Composition fee for perpetual pupils, £125, or in the following instalments: First year, £45; second year, £45; third year, £40. For attendance on the hospital practice and lectures required by the examining corporations, £45 for the first year, £45 for the second year, and £20 for each succeeding year. The latter scale of payment does not entitle the pupil to become house physician or house surgeon, or to compete for the Brown exhibitions. The fee for general subjects in dental surgery is £55, payable in two instalments; first year, £30; second year, £25.

GUY'S HOSPITAL.—*Appointments:* The house-surgeons and house-physicians, the obstetric residents, clinical assistants and dressers, are selected from the students, according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships, etc.—Open scholarship of £125 guineas, in classics, mathematics, and modern languages. Open scholarship of 125 guineas, in chemistry, physics, botany, and zoology. Six scholarships, varying in value from £10 to £50 each, for general proficiency in medical study, open to students of different years. The Joseph Hoare prizes; the Treasurer's gold medal in medicine; the Treasurer's gold medal in surgery; the Gurney Hoare prize of £25, for clinical study; the Sands Cox scholarship of £15 per annum for three years, for physiology and physics; the Michael Harris prize of £10, for anatomy.

Scale of Fees.—For the entire course of lectures and hospital practice, 125 guineas, if paid in one sum on entrance, or by two equal instalments of £68, payable at the commencement of the first winter, and of the following summer session; or payment may be made by instalments of £50, £50, and £37 10s., payable at the beginning of the first, second, and third years respectively. Fee for the dental course, 63 guineas, or in two annual instalments of 40 guineas and 23 guineas.

KING'S COLLEGE HOSPITAL.—*Appointments.*—One physician's assistant, two house-surgeons, and one physician-accoucheur's assistant appointed every six months. They are supplied with board and residence in the hospital on payment of £30 each. Assistant house-physician, assistant house-surgeon, and assistant resident accoucheur appointed every six months; in-patient clinical clerks and dressers; out-patient clinical clerks and dressers; obstetric clerks, ophthalmic, dental, and aural assistants; post-mortem clerks; assistant demonstrators and prosectors of anatomy.

Scholarships etc.—Three Warneford scholarships, each of the value of £25 per annum, two tenable for three years, and one tenable for two years; one Warneford scholarship of £25 per annum, tenable for two years, open to resident students; three junior scholarships of £20 each, tenable for one year, and open to students of the first year; one second year scholarship of £30, tenable for one year, and open to students of the second and third years; the senior scholarship of 40l., tenable for two years, and open to students of the third and fourth years; Daniell scholarship of 20l. per annum, tenable for two years, for work in the chemical laboratory; two Sambrook registrarships, each of 50l. per annum; two science exhibitions of 50l. and 25l.; two Warneford prizes of 25l. and 15l. respectively; Leathes prize; Todd medical clinical prize; Jelf medal; Tanner prize of 10l. for obstetrics. Class prizes, each of the value of 3l., are awarded annually in particular subjects.

Scale of Fees.—Payment for the entire course of hospital practice and college lectures may be made in one sum, viz., 125l. on entrance, or by the following instalments:—70l. and 60l., or 60l. on entrance, 50l. at the beginning of the second winter session, and 25l. at the beginning of the third winter session. Fees for the dental course, 95l. 1s. 6d.

LONDON HOSPITAL.—*Appointments.*—The resident and other hospital appointments are free to full students. The resident appointments consist of five house-physicians, five house-surgeons, and one accoucheurship; also two dresserships and two maternity assistantships. All these officers are provided with board and lodging free of expense. There are also—non-resident—three clinical out-patient assistants, receiving 80l. per annum each, and two registrars, each with a salary of 100l.

Scholarships, etc.—Two entrance science scholarships, value 60l. and 40l., and two Buxton scholarships, value 30l. and 20l., will be offered for competition at the end of September to new students. A scholarship, value 25l., in anatomy, physiology, and chemistry, to first and second year's students; a scholarship, value 20l., in clinical medicine; a scholarship, value 20l., in clinical surgery; a scholarship, value 20l., in clinical obstetrics; the Duckworth Nelson prize, value 10l. (biennial), in clinical medicine and surgery; the Letheby prize of 30l. for chemistry. Prizes, value 60l., to dressers of out-patients, in minor surgery.

Scale of Fees.—Perpetual fee for lectures and hospital practice, and two years' practical anatomy, payable in three instalments of 45, 40, and 15 guineas, at the commencement of the first, second, and third years respectively, 100, or if in one payment, 90 guineas. Composition fee for students entering at or before the beginning of their second winter session, their first year having been spent elsewhere, payable in two instalments of 45 and 30 guineas, 75 guineas; or if in one payment, 70 guineas. Fee for lectures alone, 50 guineas; fee for hospital practice alone, 50 guineas; dental students (general hospital practice and lectures) 40 guineas; fee for dental practice, 10 guineas. Special advantages in the shape of reduced fees are offered to full students, who, having attended classes in natural science at other places, succeed within a certain time in passing the preliminary scientific examination. The composition fee covers four years' attendance only.

ST. MARY'S HOSPITAL.—*Appointments:* There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months; all of them live, free of every expense, in the hospital. Two paid prosectors appointed annually; a demonstrator of anatomy, a medical tutor, and a resident registrar, each with a salary of £100 a year, appointed annually, and eligible for re-election. Clinical clerks and dressers.

Scholarships, etc.—Three scholarships in natural science, tenable for three years, value £120; an exhibition in natural science of £20, tenable for one year; a scholarship in anatomy of £20, tenable for one year; a scholarship in pathological anatomy of £40, tenable for one year. At the end of each session prizes ranging in value from £2 2s. to £4 4s. are given for proficiency in particular subjects.

Scale of Fees.—For unlimited attendance on lectures and hospital practice, 125 guineas if paid by instalments, or 119 guineas if paid in one sum. Fee for hospital practice and lectures required by the examining bodies, 107 guineas in instalments, or 101 guineas in one sum. Fee for dental students, 62½ guineas.

MIDDLESEX HOSPITAL.—*Appointments:* Two house-surgeons, three resident physician's assistants, resident obstetric physician's assistant. The above officers have residence and board in the hospital free of expense, but they pay on appointment fees varying according to circumstances from 10 to 30 guineas.

Scholarships, etc.—One entrance science scholarship of £50; two Broderip scholarships of £30 and £20 per annum respectively, tenable for two years, for medicine and surgery; two entrance scholarships of £25 and £20 per annum respectively, tenable for two years; John Murray medal and scholarship, awarded every third year; the Governors' prize of £21; clinical prize of £10 10s.; class prizes in particular subjects.

Scale of Fees.—General fee for the entire course of hospital practice and lectures, £90 if paid in one sum on entrance, or by instalments of £40, £35, and £20, payable at the commencement of the first, second, and third years respectively, and £10 for every additional year's attendance. Course of dental surgery, £42, or in two instalments of £30 and £15.

ST. THOMAS'S HOSPITAL.—*Appointments:* Two house-physicians, two house-surgeons, a resident accoucheur, two assistant house-physicians, two assistant house-surgeons, holding office for three or six months. The assistants are non-resident, but the other officers are provided with rooms and commons in the hospital free of expense. An ophthalmic clinical assistant, with salary of £50; surgical ward clerks, clinical clerks and dressers to in-patients and out-patients, obstetric clerks, two hospital registrars, each with a salary of £100; assistants in the dissecting-room, prosectors, pathological assistants, and assistants in the physiological laboratory.

Scholarships, etc.—Two entrance scholarships in natural

science of £100 and £60 respectively; for first year's students the William Tite scholarship of £30, and four college prizes, ranging in value from £10 to £20; for second year's students, the Musgrove scholarship of £42, and college prizes ranging in value from £10 to £20; for third year's students, three college prizes of £20, £15, and £10 respectively. In addition there are awarded the Cheselden medal for surgery, the Mead medal for medicine, the Solly medal for reports of surgical cases, the Grainger testimonial prize of £20 for a physiological essay, and the Treasurer's gold medal for general proficiency.

Scale of Fees.—For the entire course of hospital practice and lectures, £125, paid on entrance, or £130 in two payments, £70 on entrance, and £60 at the beginning of the next year; or by three instalments of £60, £50, and £30, at the beginning of the first, second, and third years respectively. The fee for the attendance on the general subjects required of students in dental surgery is for the two years £55, or by instalments, £50 for the first year, and £10 for the second year.

UNIVERSITY COLLEGE HOSPITAL.—*Appointments:* Six physicians' assistants, six house-surgeons, and four obstetric assistants are selected annually by examination from among the senior students without additional fee. They reside in the hospital, paying only for their board, and have charge of the resident patients in the absence of the physicians and surgeons. The offices of physicians' clerks, surgeons' dressers, surgical ward clerks, and ophthalmic surgeons' assistants are selected from among the pupils who are also students of the college, without additional fee.

Scholarships, &c.—Three entrance science exhibitions of 100*l.*, 60*l.*, and 40*l.* respectively, tenable for two years; Atkinson-Morley surgical scholarship of 45*l.* a year, tenable for three years; Atchison scholarship, value about 55*l.*, tenable for two years; Sharpey physiological scholarship, value about 70*l.* a year, tenable for three years; Filletter exhibition for proficiency in pathological anatomy, value 30*l.*; Dr. Fellows' clinical medal; the Liston gold medal; Alexander Bruce gold medal; Cruik memorial prize; class medals, &c.; gold and silver medals, or other prizes, as well as certificates of honour, are awarded, after competitive examinations in particular branches of study. Prizes to the value of 10*l.* will be given in the class of hygiene. The Jews' commemoration scholarship of 15*l.* for two years; the Tufnell scholarship of 100*l.* for chemistry, two years; and the Clothworkers' exhibition of 50*l.*, for two years, can also be held in the Medical Faculty.

Scale of Fees.—125 guineas, if paid in one sum at the commencement of the course, or 130 guineas if paid by instalments, as follows: First year 60 guineas, second year 50 guineas, third year 20 guineas. Hospital practice and clinical instruction, perpetual, 36*l.* 15*s.*; one year, 15*l.* 15*s.*; six months, 10*l.* 10*s.* Practical pharmacy, three months, 5*l.* 5*s.*

WESTMINSTER HOSPITAL.—*Appointments:* There are numerous dresserships and clerkships: the posts of medical and surgical registrar, each with 40*l.* a year, and of house-physician, house-surgeon, resident obstetric assistant, assistant house-surgeon, physician's assistant, surgeon's assistant, ophthalmic assistant, and assistant in the skin department.

Scholarships, &c.—Entrance scholarships, in October. The Fees, 40*l.* a year for two years, and one other, value 40*l.* Subjects—Latin, Mathematics, French or German, and Chemistry and Natural Philosophy. The Latin books the same as the June examination of the University of London matriculation—Livy, Bk. II. There are also—an exhibition, value 10*l.* 10*s.* for first year's men; a scholarship in anatomy and physiology, value 21*l.*, for second year's men; prizes for clinical medicine and surgery of 5*l.* each; the Frederic Bird medal and prize, value 15*l.*; the Chadwick prize for proficiency, value 21*l.*

Scale of Fees.—In one payment, 100*l.*; in two payments of 50 guineas each, payable on entrance and at commencement of second year respectively, or by five payments distributed over five sessions, amounting to 115*l.* There are no extras, except parts for dissection. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 45*l.*

Medical students are admitted to the practice at the following metropolitan hospitals, to which no medical school is attached; more complete particulars will be supplied on application to the various secretaries.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,

Victoria Park.—This is a large and important hospital at the East End, containing 164 beds.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom; 192 beds. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, 3*l.* 3*s.* for three months; perpetual, 5*l.* 5*s.*

HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W.; contains 21 beds, outposts, Newington Butts, Walworth, and St. John's Gardens, Notting Hill.—The practice of the hospital is open to students on payment; fee for three months' course, 3*l.* 3*s.*; for six months, 5*l.* 5*s.*; perpetual, 7*l.* 7*s.* Laryngoscopic demonstrations are given daily at half-past two.

CENTRAL LONDON THROAT HOSPITAL, Gray's Inn Road.—Twenty beds. Six clinical assistants, being either qualified practitioners or students of three years' standing, are elected to assist the surgeons. Fees for three months' attendance, 2*l.* 2*s.*; six months', 3*l.* 3*s.*

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—This hospital treats above 6,000 out-patients annually, and makes up 40 beds.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, 3*l.* 3*s.*; perpetual, 5*l.* 5*s.* Secretary: Mr. S. Whitford. There are now 104 beds in the hospital, Great Ormond Street, and 52 beds in the country branch; total, 156. The practice at the hospital has been thrown open gratuitously to pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the secretary.

THE HOSPITAL FOR WOMEN, Soho Square, W.—The hospital contains 61 beds. Clinical instruction is regularly given in the wards, and in the out-patient room daily at 10, to members of the profession and to students after their third year. Clinical clerks and assistants are appointed from time to time, application to be made to the physicians.

BRITISH LYING-IN HOSPITAL, Endell Street, St. Giles's.—Twenty-five beds. This institution receives women only as midwifery pupils. The fee for the course of three months is 10*l.* 10*s.* Pupils who prove themselves competent receive a certificate signed by the physicians enabling them to practise midwifery.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W.—Fifty-two beds.

ROYAL LONDON OPHTHALMIC HOSPITAL, Bloomfield Street, Moorfields, is the largest of its class in the metropolis, and contains 100 beds.

LONDON FEVER HOSPITAL, Islington.—280 beds.

GREAT NORTHERN HOSPITAL, Caledonian Road.

WEST LONDON HOSPITAL.—A well-appointed hospital at the western extremity of the metropolis in the Hammer-smith Road, containing 60 beds. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr. Gilbert, at the hospital.

BETHLEM HOSPITAL.—This hospital is open for the admission of two resident medical students who have recently obtained their diplomas to practise medicine and surgery, for the acquisition of knowledge regarding the insane. The next election takes place in October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

ROYAL FREE HOSPITAL, Gray's Inn Road.—This hospital contains 150 beds. Of the smaller metropolitan hospitals few offer a more extensive field for students in medicine and surgery. At this hospital the students at the London School of Medicine for Women take out their medical and surgical practice. Clinical clerkships and surgical dresserships are held by these students. The fees payable are £20 the first, and £15 each succeeding year. The *School of Medicine* is situate away from the hospital. The composition fee for all classes and lectures, except clinical, is £80 in one sum, or three payments of £40, £30, and £15.

PROVINCIAL MEDICAL SCHOOLS.

BIRMINGHAM—QUEEN'S COLLEGE.—Students are admitted—(1) as matriculated students who enter for their entire medical education; (2) as occasional students for one or more courses of lectures; (3) as junior students, to prepare for the preliminary examinations of the licensing boards.

Scholarships, Prizes, &c.—The Sands Cox prize, value £20.

Open to students who have completed their curriculum. Subjects:—Medicine, Surgery, and Midwifery. Two Ingleby scholarships for obstetric medicine and surgery and diseases of women, Sydenham and Queen's scholarships of £30. The Warden's prize, value £5 5s., for first year's students, for general proficiency. The Percy prize, value £5 5s., for German.

Fees.—College fees for all lectures amount to 60 guineas, payable by two equal instalments.

Hospital practice is obtained at the General and Queen's Hospitals, which have been amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds, and the staff attached is of a very high order.

All students will be required to attend six months alternately at each hospital, as directed by the Clinical Board, excepting students who enter the hospital for six months only.

Clinical Prizes.—The following prizes are given annually: Senior medical prize for third and fourth year's students, first prize, £5 5s.; second prize, £3 3s. Senior surgical prize for third and fourth year's students, first prize £5 5s.; second prize, £3 3s. Junior medical prize, for second year's students, first prize, £3 3s.; second prize, £2 2s. Junior surgical prize for second year's students, first prize £3 3s.; second prize £2 2s. Midwifery prize £4. Medals and certificates are awarded in each class. The examinations for all the appointments and prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, £42.

BIRMINGHAM.—THE MASON COLLEGE.—The magnificent institution, founded, built, and endowed by the late Mr. Josiah Mason, and devoted to the spread of scientific information, is now open for the reception of students under a staff of eminent professors. Special facilities are offered at the college to intending medical students to complete the preliminary scientific work, without which they cannot hope to succeed in obtaining any one of the higher University degrees. Classes have been formed in chemistry, physics, biology, physiology, and practical work in all these subjects is carried out in well appointed and commodious laboratories. The fees for each course of lectures are payable in advance, and arranged on a scale of the most moderate kind, varying from half a guinea to three guineas for the whole. Further particulars will be found in the advertisement pages of the present number.

BRISTOL SCHOOL OF MEDICINE (University College).—Attached to this school, where there is ample provision for education and practice, are two well-appointed hospitals—the Royal Infirmary containing 250 beds, and the General Hospital with 154 beds. Competitive examinations are held amongst students of the first, second, and third years respectively, and prizes of money, instruments, and books are awarded annually. The certificates of this school are accepted by all the examining boards. Medical and surgical hospital practice and clinical lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional prizes are annually offered for competition amongst the students. The existing medical school is affiliated to University College, Bristol.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in the medical school to first, second, and third year's students, and also in practical anatomy. At the Royal Infirmary—Supple's medical prize, a gold medal and £7 7s.; Supple's surgical prize, as the medical; Clark prize (interest of £100) for third year's students; pathological prize, £3 3s. At the General Hospital: Martyn memorial scholarship, £20; Clarke scholarship (surgical), £15; Sander's scholarship (interest of £500), medicine and surgery; Lady Haberfield's prize (interest of £1,000), for general proficiency.

Clinical lectures are given at both institutions three and four times a week.

Fees.—School fees for unlimited attendance on all courses of lectures except comparative anatomy, £63. For hospital practice, 35 guineas.

LEEDS SCHOOL OF MEDICINE.—Clinical lectures are given by the physicians and surgeons attached to the General Infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the Infirmary by the surgeons in each department, where also are obtainable six clinical clerkships and eight dresserships. Besides the infirmary there is a large dispensary and a fever hospital, both of which are open to students of the school. Students at this school have excellent opportunities of acquiring a thorough insight of psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, and Dr. Major lectures on mental diseases during the summer. The systematic lectures are given at the school, and the clinical lectures at the asylum, which now accommodates 1,500 patients.

There is the Hardwicke scholarship in clinical medicine, value £10, the Thorp, in forensic medicine, value £10; three surgeons' clinical prizes, of £8, £5, and £3 respectively. Silver and bronze medals, books, and certificates of honour are awarded for proficiency in particular subjects.

The composition fee for attendance upon all the required courses of school lectures is £50 5s., to be paid on entrance; or £27 6s. on entrance, and a second sum of £27 6s. twelve months afterwards.

At the General Infirmary the perpetual fee for medical practice and clinical lectures is £26 5s. The same amount is charged for the perpetual attendance on the surgical practice and clinical lectures. These fees are not included in the composition fees for lectures, and are payable separately.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—The infirmary attached to this school, which contains 300 beds, with 40 special wards for the treatment of diseases of women, is, perhaps, second to none in England in its general appointments, and the facilities it offers to students for gaining practical knowledge.

A payment of 60 guineas on entrance, or in two equal instalments (one-half on entrance, and the remainder within twelve months), entitles the student to attendance on all the necessary lectures and demonstrations. The Royal Infirmary contains nearly 300 beds. There are special wards for the treatment of uterine and other diseases of women. During the year 1880, 2,600 patients were admitted into the infirmary; the number of out-patients was 5,300. The Lock Hospital, adjoining the infirmary, contains 60 beds; during the past year 658 males and females were admitted as in-patients.

Two house physicianships and three house surgeons, tenable for six months, and open to pupils of the school who have obtained a legal qualification; clinical clerks and dressers; post-mortem clerks.

Two Roger Lyon Jones scholarships, each of £21, for two years, one awarded as an entrance scholarship, and the other being open to students who have completed their second year; the Torr gold medal for anatomy and physiology; the Bligh gold medal for anatomy and physiology. School medals and certificates of honour are awarded for proficiency in certain groups of subjects.

The fee for a perpetual ticket for hospital practice is £42, and may be paid in two equal instalments (one-half on entrance, and the remainder within twelve months).

MANCHESTER.—VICTORIA UNIVERSITY, OWENS COLLEGE SCHOOL OF MEDICINE.—This school, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a faculty of science as well as of medicine, with departments of law and arts. Since the amalgamation, a new medical school has been built on the most improved principles, at the western extremity of the College Estate. On the ground floor are two large lecture theatres, a library, and a museum. Over the lecture theatre is a dissecting-room, and over the library a physiological laboratory. The course of instruction afforded to students is thoroughly complete. Three of the most important chairs—those of anatomy, physiology, and chemistry—are held by professors who entirely devote their time to the work of instruction. Students wishing to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are offered for competition in this branch as an incentive to original research. The hospital practice is taken out at the Royal Infirmary, which contains 315 beds. The Monsall Fever Hospital and Cheadle Lunatic Asylum also afford teaching facilities of great importance.

Appointments.—Resident medical officer, Royal Infirmary, £250 per annum; resident medical officer at Cheadle, £150; resident medical officer at Monsall, £200; resident surgical officer, £150; eight house surgeons, six months each; four house physicians, for six months each; a registrar; a pathological registrar—£100 each.

Scholarships, Prizes, &c.—Turner scholarship, £25, for third year's men; Platt physiological scholarship (two), £50 each, two years; one annually for physiology. Platt exhibitions (two), £15 each, for physiology. Dumville surgical prize, £20; examination in clinical surgery. Prizes of books, instruments, &c., varying from £5 5s. to £3 3s., for third, second, and first year's students. Entrance scholarships: Dauntsey medical scholarships.—Candidates not to be over 25 years of age, may be registered, but must not have studied at any medical school; value about £100, for one year. Successful candidates must at once enter on full medical course in the Owens College. Examination takes place in October. Subjects: General and comparative anatomy, physiological botany, chemistry, including practical work, either mathematics or Latin. Gilchrist scholarships: Three of £50, for three years. One is annually awarded to candidates standing highest at matriculation of London University in June (provided he be in the honours division); failing such, two of £25 to the two candidates standing highest in the first division; candidates must be between 16 and 20 years of age. There are also grammar school scholarships.

Fees.—Composition fee, £63, or two sums of £31 10s. each. Hospital practice: composition fee £42, or two instalments of £22 each. Further information may be obtained of Professor

Gamgee, Dean of the School, or of the Registrar, Mr. J. Holme Nicholson, Owens College, Manchester.

NEWCASTLE-ON-TYNE COLLEGE OF MEDICINE.—This school is a department of the University of Durham, and contains ample provision for acquiring a sound education and practical experience at the bed-side. It is smaller than some of the provincial schools, but sound and successful teaching, attended with remarkably good examination results, are fast bringing it on a level with its competitors in point of numbers.

The Infirmary contains 230 beds. There are special wards for diseases of the eye, for lock cases, male and female, and for children. Pathological demonstrations are given as opportunity offers. Practical midwifery can be studied at the Newcastle Lying-in Hospital, which contains 12 beds. Opportunities for practical study are also afforded by the Dispensary, Fever Hospital, Eye Infirmary, Children's Hospital, and Coxlodge and Dunston Lunatic Asylums. Lectures are given on Psychological Medicine at the Coxlodge Lunatic Asylum by Mr. R. H. B. Wickham, Medical Superintendent. Mr. H. E. Armstrong lectures on Public Health.

Appointments.—An Assistant-Curator of the Museum is annually appointed from among the senior students, and receives £12 as an honorarium. Assistant Demonstrators of Anatomy, Prosectors for the Lectures on Anatomy, Assistant Physiologists, Pathological Assistants, and Assistants to the Dental Surgeon are also elected. Four times in the year two Resident Medical Assistants, two Resident Surgical Assistants, three Non-resident Clinical Clerks, and sixteen Non-resident Dressers (eight for the In-patient, and eight for the Out-patient Department), are nominated by the Medical Board, and, if approved, appointed by the House Committee for three months. The Medical and Surgical Assistants are provided with apartments and board in the Infirmary, on payment of £5 5s. for three months.

Scholarships, &c.—University Scholarship, value £25 a year, for four years, for proficiency in Arts, awarded annually at beginning of winter session to perpetual students in their first year only. The Dickinson Memorial Scholarship, value £15 annually, for Medicine, Surgery, Midwifery, and Pathology; open to perpetual students who have passed the primary examination of a licensing body. The Tulloch Scholarship, interest of £400 annually, for Anatomy, Physiology, and Chemistry. The Chariton Memorial Scholarship, interest of £700 annually, with Gold Medal, open to full students entered for the class of Medicine at end of winter session. The Gibb Scholarship, interest of £500 annually, for Pathology, at end of summer session. As the end of each session, a Silver Medal and Certificates of Honour are awarded in each of the regular classes.

Fees.—Composition fee for lectures £63, in one sum, or two instalments of £36 15s. each, or three instalments of £31 10s., £20 5s., and £21. Royal Infirmary perpetual fee, £26 5s.

Further information may be obtained from the Registrar, Dr. Luke Armstrong, Newcastle-on-Tyne.

SHEFFIELD SCHOOL OF MEDICINE.—Students at this college obtain excellent instruction in medical and surgical practice at the General Infirmary, which contains 180 beds, and is provided with a museum and pathological and post-mortem theatres. The fees for perpetual attendance are £15 15s. for medical, and £21 for surgical practice; for twelve months' medical and surgical practice, each £10 10s., and for six months, £8 6s. each. There is also the Sheffield Hospital and Dispensary, containing 104 beds, and is recognised by the College of Surgeons and the Hospital for Diseases of Women, to which students are admitted. The perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £45. Prizes to the value of £30, and certificates of honour, are given annually. Some of the lecturers, and other local members of the profession, receive house pupils; such a mode of residence will be found far preferable to life in ordinary lodgings.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—This institution is one of the largest in the English provinces, and contains 200 beds. It has no school proper, although it contains accommodation for resident pupils, and clinical lectures are delivered daily by members of the staff. These, together with the practice obtained here, which is of a very varied and valuable character, are recognised by all the examining boards.

Inclusive fees: Perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately, on payment of half the above fees.

EXTRA-ACADEMICAL INSTITUTIONS.

LONDON SCHOOL OF DENTAL SURGERY.—This institution is situated in Leicester Square. General fee for special lectures required for the curriculum, £15 15s. The Saunders Scholarship of £20 per annum, and prizes, are open for competition. In connection with the above is the Dental Hospital of London. Fees for two years' hospital practice, £15 15s. Fees for lectures and practice, £31 10s.

NATIONAL DENTAL COLLEGE.—This is a more modern

institution than the one in Leicester Square, having been open but a few years. In connection with the College is the National Dental Hospital, situate in Great Portland Street, which was established several years before the school. The teaching at this school is recognised by the Royal College of Surgeons for the dental diploma, and lectures and demonstrations are given similar to those at the other dental school. **Fees.**—General fee for special lectures required by the curriculum, 12l. 12s.; fee for the two years' hospital practice required by the curriculum, 12l. 12s. Total fee for the special lectures and hospital practice required by the curriculum, 25l. 4s.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures are delivered on—(1) Physics in relation to chemistry and pharmacy; (2) Inorganic chemistry; (3) Organic chemistry, botany, and materia medica. These lectures are delivered on Thursday, Friday, and Saturday mornings, at nine o'clock. The laboratories are open from ten o'clock in the morning until five in the afternoon daily, except on Saturdays, when they are closed at two o'clock. Fee for ten months, according to hours of attendance, 12 to 25 guineas; for shorter terms in proportion. Each student is expected to attend every lecture of the course for which he has entered, or to state the cause of absence to the professor or to an assistant.

COOKE'S SCHOOL OF ANATOMY AND PHYSIOLOGY.—This is established for private tuition, and is situate close to University College, its principal being Mr. Thomas Cooke, F.R.C.S., Senior Assistant-Surgeon to the Westminster Hospital, whose private address is at 16 Woburn Place. The whole of the anatomy (on the dissected body), of physiology (with microscopical preparations, and such experiments as the law permits), and operative surgery (on the dead body), are gone through carefully every three months. **Fees.**—Three months, 3 guineas; six months, 4 guineas; for the higher examinations, with special supplementary class, 5 guineas. There is a well-appointed dissecting-room near the school.

SOUTH LONDON SCHOOL OF PHARMACY.—This school, which has accommodation for 120 students, is situated at Kennington Cross, and decidedly the most popular institution for the study of practical pharmacy and chemistry in London. Instruction is also given in analytical chemistry for the purpose of qualifying gentlemen in search of appointments under the Public Health and Adulteration of Food Acts, by the principal, Dr. Muter. Lectures are delivered daily in the laboratory, and each student is required to practically illustrate that he grasps the subject taught as the lecturer proceeds. The percentage of pupils passing at the examination is exceptionally high from this school. The winter session commences a fortnight earlier than the medical schools.

SCHOOL OF HOMOEOPATHY.—Homoeopathy has now a school for students, which is situate in Great Ormond Street, where lectures and instructions according to homoeopathic principles are given by duly qualified members of the medical profession, and where students who believe in the *similia similibus curantur* theory can be taught according to their bent. The winter session at this school opens on October 2nd.

II.—QUALIFICATION.

THERE are in England seven examining bodies which confer qualifications to practise medicine. Four of these are Universities granting degrees; two are Colleges of Physicians and Surgeons respectively, granting registrable diplomas; the remaining institution is the Society of Apothecaries. The following account of these institutions includes particulars of the regulations under which the various qualifications are granted:—

THE ENGLISH UNIVERSITIES.

The distinction of a university degree carries with it so many advantages, social and professional, that every student who can possibly obtain so desirable a qualification will be consulting his best interests by straining every point in its favour. Of late years the facilities for obtaining the highest class degrees have so much increased,

that an earnest and hard-working student not afraid of a good deal of extra labour, and with even average abilities, may readily gain for himself the distinguishing mark of culture conferred by graduation at one of the older seats of learning. The numerous scholarships open to general competition, and awarded at Oxford and Cambridge, &c., for proficiency in many of the subjects included in the preliminary medical curriculum, offer a ready means of meeting the extra expenses to be necessarily incurred at a university, as compared with the cost of ordinary qualification; and to this must be added the similar money prizes which, with only a slight additional labour, may be gained at the various hospital schools of medicine, and which will suffice to meet the major part of extra-academical outlay. Moreover, the liberal alterations introduced of late years into the regulations for the medical degrees of Durham University present a means whereby, with the sacrifice of less than twelve months of time spent "in residence" within the university bounds—and even this can be passed in regular medical study at the Newcastle-on-Tyne School of Medicine—any duly registered medical student can proceed to the examination for the M.B. degree of that University. On one point there is a common agreement among the universities, that, viz., they will admit no one to their earliest examinations who cannot show himself to have received a sound preliminary education in arts; and the necessity for this on the part of future medical practitioners is recognised no less now by all the examining boards of the kingdom. Whatever the future ambition of the student, it will be wisest for him to be prepared with a view to ultimate graduation at a university, as thus will he be most effectively fitted to pursue the path leading to that goal, should opportunities arise for doing so. We will now briefly detail the principal features peculiar to the different universities in respect of graduation at each.

Oxford.

Every student in medicine must pass all the examinations for the degrees of B.A., and date the commencement of his medical studies from the final examination in arts or science. For the degree of B.M. two examinations must be passed, the first including Anatomy and Physiology (Human), Comparative Anatomy (chiefly the entozoa), and Physiology, Botany, Chemistry (theoretical and practical), and Physics, with Mechanics. All candidates, however, who have obtained honours in the School of Natural Science, or have passed the University examination in Chemistry, Mechanics, and Physics, are not required to offer these subjects again at the first M.B. At the second examination he is examined in two of the ancient authors—Hippocrates, Aretæus, Galen, and Celsus—and in some one modern author, as Morgagni, Sydenham, or Boerhave, as well as in the Principles and Practice of Medicine and Surgery, the Diseases of Women and Children, &c., &c. The first, or scientific, examination may be passed immediately; and two years must elapse after passing the first, prior to the final examination for the same degree. A dissertation has to be publicly read three years after obtaining the M.B. before being eligible for the M.D. The medical examinations take place annually in Trinity Term.

Scholarships of value from £60 to £100 are obtainable at Christ Church, Magdalen, and other Colleges, by competitive examinations in natural science. Each year a Radcliffe Travelling Fellowship is competed for by those who, having taken a first-class at any of the public examinations of the University, or having obtained some University prize or scholarship open to general competition, propose to graduate in medicine. The Travelling Fellows receive £200 a-year for three years, half this period being spent in study abroad.

The facilities for the study of medicine at Oxford are considerable, but no attempt to utilise them is made or encouraged.

Cambridge.

At the University of Cambridge, five years of medical

study are required for the M.B., unless the student has graduated with honours as B.A., when four years suffice. He must have resided nine terms in the University, and have graduated in arts. There are three examinations for this degree. The first is in chemistry, physics, and botany; the second in anatomy (human and comparative), physiology, and pharmacy; and the third, in the usual practical subjects. Subsequently to the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations, and an essay has to be written *extempore*. There is also a degree of Master in Surgery, for which the candidate has to attend extra courses of lectures on anatomy and surgery. An examination in so much of State Medicine as is required by medical officers of health will in turn be held. The yearly expenditure of a student who keeps his terms by residence in a college is from £150 to £200 a-year. This, however, may include all payments to the University and the college—all fees, as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are very small. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

London.

The medical degree of London University is given to all and everyone who succeeds in satisfying the examiners of fitness to receive it. Women, as well as men, can proceed to it, irrespective of any consideration of residence or place of instruction, provided this has been obtained at a properly-appointed hospital or hospitals.

Those students who intend to graduate at the London University should arrange their studies to pass the preliminary scientific examination *before commencing their regular medical studies*, taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained which will go to clear the way for first year's studies, which would otherwise be much encumbered.

The preliminary scientific examination commences on the third Monday in July, and no candidate is admitted to it unless he has completed his seventeenth year, and has passed the matriculation examination. The subjects on which he will be examined are—Inorganic chemistry, experimental physics, botany, vegetable physiology, and zoology. Candidates who shall pass in all these subjects, and shall also pass at the same time in the pure mathematics of the first B.Sc. examination, or shall have previously passed the first B.A. examination, shall be considered as having passed the first B.Sc. examination also. There are in this, as in every other stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly prized distinctions in various branches, such as valuable scholarships, exhibitions, and prizes. The medical and scientific degrees of the University are—Bachelor and Doctor of Medicine, Bachelor and Master in Surgery, and Bachelor and Doctor of Science.

For the M.B. degree there are three professional examinations, namely, the preliminary scientific, the intermediate, and the final M.B. Before proceeding to the intermediate examination, which is held once a year, beginning on the last Monday in July, the candidate must have passed the preliminary scientific examination at least one year previously, and must produce certificates—1. Of having completed his nineteenth year; 2. Of having been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the following subjects: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases

peculiar to Women and Infants, Surgery, Medicine ; 3. Of having dissected during two winter sessions ; 4. Of having attended a course of Practical Chemistry ; 5. Of having attended to Practical Pharmacy, and having acquired a practical knowledge of the preparation of medicines. Candidates are examined in Anatomy, Physiology and Histology, Materia Medica and Pharmaceutical Chemistry, Organic Chemistry. Candidates must show a competent knowledge in all the subjects. The examinations are conducted by printed papers and *visd voce* interrogation, by demonstration from preparations and specimens, and by dissections.

For the final or M.B. candidates must produce certificates—1. Of having passed the intermediate examination in medicine at least two years previously ; 2. Of having subsequently attended a course of lectures on each of two of the subjects for which he had not presented certificates at the intermediate examination ; 3. Of having conducted at least twenty labours ; 4 and 5. Of having attended the surgical and medical practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on clinical surgery and clinical medicine ; 6. Of having, after having attended surgical and medical hospital practice for at least twelve months subsequently to passing the intermediate examination in medicine, attended to practical medicine, surgery, and midwifery, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of the hospital practice prescribed in 4 and 5 ; 7. Of having acquired proficiency in vaccination. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. Candidates are examined in General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The examinations include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. The examinations are conducted by printed papers and *visd voce* interrogations ; by practical examinations in obstetric preparations and apparatus ; by examination and report on cases of medical patients in the wards of a hospital ; demonstrations from specimens and preparations. Candidates are expected to write prescriptions in Latin without abbreviations.

The regulations relating to the examination for honours, prizes, &c., and to the M.D. and B.S. examinations may be obtained from the Registrar of the University, Burlington Gardens, W.

A special examination is held once in every year in subjects relating to public health, to which those candidates only are admitted who have passed the M.B. examination at least one year previously. Candidates will be examined in chemistry and microscopy, as regards the examination of air, water, and food ; meteorology, geology, physics, and sanitary apparatus, vital statistics, hygiene, and sanitary laws, full particulars of which may be obtained from the Registrar.

All the medical degrees of the London University being open to women, valuable scholarships have been founded for their special benefit in connection with them.

University of Durham.

Two licences and three medical degrees are conferred by this University—viz., Licences in Medicine and Surgery, with degrees of Bachelor of Medicine, Master of Surgery, and Doctor of Medicine. A certificate of proficiency in sanitary science is also awarded.

With regard to the degree of Bachelor of Medicine, no one will be admitted to that degree unless he has kept one year's residence at the Durham University College of Medicine, and in the case of non-university men an additional Arts examination to the professional examination must be passed.

Every candidate must be not less than twenty-one years of age, and must produce certificates of age, of registration as a student in medicine in the books of the General Medical Council, of good moral conduct, and of attendance on the usual lectures and hospital practice. In addition to the certificate of registration he must produce proof of having passed a somewhat higher Arts examination than those usually possessed before registration.

Candidates, however, who, at the commencement of their professional education passed the Arts examination for registration only, may pass in the extra subjects required either before or after presenting themselves for the first examination for the degree, but must do so before presenting themselves for the second examination.

There are two professional examinations, the first being held twice yearly, viz., in October and April, and the second twice yearly, in June and December. The subjects of the first examination are Anatomy, Physiology, Chemistry, Botany. The subjects of the second examination are Medicine, Surgery, Midwifery and Diseases of Women and Children, Pathology, Medical Jurisprudence, Materia Medica and Therapeutics, Public Health. The first examination will commence on Dec. 4th, 1882, and on April 23rd, 1883. The second examination will commence on Dec. 4th, 1882, and on June 18th, 1883. The successful candidates for the first and second examinations for the degree of Bachelor in Medicine will be arranged in three classes—in the first and second (Honours), according to merit ; and in the third (or Pass) in alphabetical order.

Candidates who have completed part of their curriculum elsewhere may pass their first examination *previously* to entering at Newcastle-upon-Tyne, and are recommended to commence their year of residence at Newcastle-upon-Tyne at the beginning of the winter session.

Full particulars relating to the M.D. (which is conferred under certain conditions without residence on senior practitioners) B.S. and M.S. degrees may be obtained from the Registrar.

Royal College of Physicians of London.

Under the remodelled scheme of examination for the Licence of this College, which is a qualification to practise medicine, surgery, and midwifery, candidates are required to pass *three* examinations in all cases in which medical studies commenced subsequently to March 25, 1880. The *first* may be taken immediately after registration, and includes chemistry (with physics), materia medica, pharmacy, botany, and osteology. The *second* can be passed eighteen months after the first ; subjects—anatomy and physiology. The *third* after 45 months of study, and not until two years after the second. It includes anatomy, medical and surgical pathology, morbid anatomy, medicine and surgery, midwifery and diseases of women, forensic medicine, hygiene, and therapeutics.

Of the 45 months of professional study, one winter and two summer sessions may be passed in either of the following ways : 1. Attending the practice of a hospital, infirmary, or other institution recognised by the College. 2. Receiving instruction as the pupil of a legally qualified practitioner, having opportunities of imparting a practical knowledge of medicine, surgery, or midwifery. 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced *before* registration, except in the cases of chemistry, materia medica, botany, and pharmacy, will not be recognised.

Certificates required: First Examination.—Evidence of having been registered as a medical student by the General Medical Council : and of having received instruction in chemistry, including chemical physics (i.e., heat, light, and electricity), in practical chemistry, in materia medica, in botany, and in practical pharmacy. (This examination includes osteology as well as the subjects named.)

Second Examination.—Evidence of having passed the first examination; of having completed, after registration as a student, eighteen months of professional study at a recognised school or schools; and of instruction in anatomy and physiology.

Third Examination.—Evidence of being twenty-one years of age; of moral character; of having passed the second examination; of having been engaged in professional study not less than forty-five months; and of instruction in the remaining subjects of study mentioned in the tables, which will be supplied on application at the College.

The Membership of the College is conferred after examination, which is conducted as follows:—Thursday: From 2 to 6, by written questions on medical anatomy, and on the principles of medicine. Friday: From 2 to 6, by written questions on the practice of medicine, including the principles of public health, and on psychological medicine. Saturday or Monday: The candidate's practical knowledge will be tested, either at the College or in the medical wards of an hospital. Tuesday and Wednesday: By examination *viva voce*. This examination will commence on the last Thursday but one in January, April, July, and October.

Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British Colony, or who shall have obtained a foreign qualification entitling him to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study, and the examinations to be undergone previously to graduation shall have been adjudged by the Censors' Board to be satisfactory, shall, if the Censors shall think fit, be admitted to the pass examination. The nature and extent of this examination shall, in the case of each candidate, be determined by the Censors' Board.

Under certain conditions the membership is to be obtained by practitioners over forty years of age without previously passing the examination for the licence, of which proof must be given by all other candidates except graduates in medicine as above described. But Licentiates admitted before February 16, 1859, and extra Licentiates otherwise may be admitted Members by a vote of the College.

The fees for the licence are £15 15s., and for the membership £31 10s.

Royal College of Surgeons of England.

The College of Surgeons requires every candidate for its Fellowship and Membership to pass two examinations, and in the case of candidates who commence their professional education on or after October 1st, 1882, proof must be adduced of having passed an examination in elementary anatomy and physiology conducted by their teachers at the several medical schools at least six months before their presenting themselves for the primary. Such candidates also will not be admitted to the second or pass examination until after the expiration of two years from the date of passing the primary, except under circumstances which are particularised thus:—

1. When a candidate, before presenting himself for the primary examination, shall possess a recognised degree or diploma in medicine or surgery, or shall have completed the curriculum of professional education for the diploma.

2. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the primary examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the primary examination for the Fellowship; it being required in such case that not less than one year of attendance on the surgical practice of a recognised hospital shall intervene between the date of his passing the primary examination for the Fellowship and the date of his presenting himself for the second or pass examination for the diploma of Member.

3. In the case of a candidate who, having commenced

his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance, shall fail to pass the primary examination at the end of his second winter session of attendance at a recognised medical school; provided that in his case not less than one year shall elapse between the date of his passing the primary examination and the date of his presenting himself for the second or pass examination for the diploma of Member.

4. When a candidate, owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the primary examination on the completion of his second year of professional study.

5. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the primary examination on the completion of his second year of professional study; it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

The regulations affecting "referred" candidates have also undergone recent amendments by which the conditions under which subsequent study must be pursued are more rigidly defined.

The second or pass examination includes a written, *viva voce*, and practical test in surgery, surgical anatomy, pathology, medicine and midwifery, but candidates can claim exemption from examination in medicine and midwifery under the following conditions, viz.:—

1. The production by the candidate of a degree, diploma, or licence in medicine and midwifery, entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in medicine or midwifery of a colonial or foreign University approved by the Council of the College.

2. A declaration by the candidate, prior to his admission to the final examination for Membership or Fellowship, that it is his intention to obtain either of the qualifications in medicine and midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

Candidates for the Fellowship must be twenty-five years of age, and must pass two examinations also, the primary including comparative anatomy and physiology to some extent as well as human. The fee for the membership is £16 15s., a further sum of £5 5s. being paid before admission to the primary examination. In cases of rejection a further fee of three guineas is required prior to re-examination.

The Apothecaries' Society of London.

Examinations are held every week during the year by the Apothecaries' Society, and licences are granted by it admitting to the practice of medicine in the United Kingdom, as well as certificates which entitle the holders to dispense medicines. A four years' course of study is required for the licence, and two examinations must be passed: the first, or primary, on anatomy, physiology and histology, chemistry, materia medica, and botany; the second, or final, in medicine, therapeutics, pathology, midwifery with diseases of women and children, forensic medicine, and toxicology. Graduates in medicine of British Universities are admitted to a modified examination, which includes a clinical and practical test in medicine, pathology, and midwifery. Every candidate is examined practically and *viva voce* at both examinations, and in all the subjects; and is required to produce proof of attendance on the classes and lectures included in the full medical curriculum, surgery excepted. The fees payable are three guineas on entering for each examination, none of which is returned to rejected candidates. The fee for certificates to dispense is two guineas.

HOURS OF THE INTRODUCTORY LECTURES*To be delivered at the different Metropolitan Schools.*

St. Bartholomew's Hospital: None. Session commences Oct. 2nd.
 Charing Cross Hospital: None. Session commences Oct. 2nd.
 St. George's Hospital: Dr. Herbert Watney, Oct. 2nd, at 4 p.m.
 Guy's Hospital: None. Session commences Oct. 2nd.
 King's College Hospital: Rt. Hon. W. H. Smith, M.P., Oct. 2nd, at 4 p.m.
 London Hospital: Prof. Hutchinson, Oct. 2nd, at 8.30 p.m.
 St. Mary's Hospital: Dr. Chambers, Oct. 2nd, at 3.30 p.m.
 Middlesex Hospital: R. W. Lyell, Esq., Oct. 2nd, at 3 p.m.
 St. Thomas's Hospital: Dr. Sharkey, Oct. 2nd, at 3 p.m.
 University College: M. Beck, Esq., Oct. 2nd, at 4 p.m.
 Westminster Hospital: Dr. Haviland Hall, Oct. 2nd, at 3 p.m.

Ireland.**I.—EDUCATION.**

THE system of medical teaching in Ireland—especially in Dublin—is entering on a new phase, by reason of the thorough and most necessary reforms contained in the new scheme of education and examination which the Irish College of Surgeons has decreed within the past year. The future arrangement will be substantially as follows:—

1. The student will not be allowed, as heretofore, to defer his examination in general education until the eve of his final examination for his qualification to practice, but must pass his "preliminary," and register as a medical student not later than a fortnight from his commencing medical study.

2. The student will no longer be obliged or allowed to defer, as in times past, his first professional examination until the end of his third year of study. He will have to pass an examination at the end of each of his four years, and his course of education will thus be graduated from the elementary subjects to those more advanced and practical.

3. It will no longer be possible for the student to complete his course of study in a less period than three years and nine months, but the first of these years will be devoted to preliminary scientific studies, which may be worked at without coming to a medical school. No lecture or hospital attendances are required during this first year, but the student must prove that he has not been idle by passing an examination at its termination.

4. The payment of fees for lectures, &c., cannot any longer be deferred beyond one year, as the certificates of attendance must be produced for the examination which is to be passed at the end of that period.

5. The proofs of actual attendance at lecture and hospital will no longer be lax and unreliable, but will be stringently enforced.

These reforms are now entering on their trial, and we are confident will effect a most salutary change in the Irish medico-educational system.

COST OF EDUCATION IN IRELAND.

Should the student proceed on his own account, the lectures necessary for the diplomas of the Colleges of Physicians and Surgeons in Ireland will amount to about £75; hospital attendance, according to the new scale of fees, £36; lying-in hospital, from £4 4s. to £7 7s. These, with the diploma fees of £26 6s. for the College of Surgeons, and £15 15s. for the College of Physicians, represent the essentials. Thus, the absolute payment will amount to somewhere about £100, taking the minimum mode of payment. In addition to this sum are to be considered the payment for "grinding" or "coaching," by no means necessary to any industriously inclined student.

The fixed sum is at present for private teaching £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary, say from £140 to £160 on a moderate scale.

This sum, or something like it, will secure to the pupil the advantage(?) of being "apprenticed" to a teacher who will undertake all monetary responsibility for his education, and may be able to give him some special advantages as his own pupil at hospital, but the so-called apprenticeship is sometimes a simple contract for payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice. Most of the apprenticeship holders will accept payment by instalments.

DATES OF ENTRY IN IRELAND.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the Session really does date from the 1st of November, and the entry of names may be delayed by the dilatory until the 15th of the same month.

The student then begins work, attending hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and discussions. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

LECTURE ATTENDANCE IN IRELAND.

The system heretofore existing under which a student could obtain unlimited certificates of "diligent" attendance on lectures and hospital in Ireland, though he might never have seen the inside of the lecture theatre, or be able to recognise the professor on meeting him in the street, has, happily, been put a stop to within the past year. The Council of the Irish College of Surgeons has passed ordinances under which the actual number of lectures delivered and attended must be guaranteed not only the teacher, but by the registrar of the school, and by the student himself, who will be required to sign a declaration that if any statement made in his certificate turns out to be untrue, he will deliver up his diploma to be cancelled. The method of checking attendances at school and hospital has also been revised and made more stringent, so that evasion of the rules will be in future very hazardous. We believe this new system will in future be rigorously enforced, so that sham certificates may be looked upon as a thing of the past.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

THE clinical hospitals of Dublin are 10 in number, exclusive of the Cork Street Fever Hospital, two lying-in hospitals, two ophthalmic hospitals, the Children's Hospital in Pitt Street, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital and any school he wishes.

The Names of the Professors, Lecturers, and Hospital Staff of the following Hospitals and Schools are not included in this column, being found in the Advertisement of each Institution in another part of this issue.

DUBLIN UNIVERSITY SCHOOL OF PHYSIC.—Every student must be matriculated by the Senior Lecturer, for which

a fee of 5s. is payable; but he need not attend any of the Arts courses unless he desire to obtain a licence or degree in medicine or surgery. No student can matriculate unless he has passed the Entrance Examination in Trinity College, in the Royal College of Surgeons of Ireland, or some other examination recognised by the General Medical Council. No student can be admitted for the Winter Courses after the 25th November.

Medical Scholarships.—Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and institutes of medicine, chemistry, materia medica, botany, experimental physics, and comparative anatomy. The Board of Trinity College have recently passed orders—1. That three-fourths of the lectures must be attended. 2. That a daily roll be called by each Professor.

THE ROYAL COLLEGE OF SURGEONS' SCHOOL OF SURGERY is attached by charter to the Royal College of Surgeons, and has existed as a department of the College for nearly a century. It is carried on within the College buildings, and is specially subject to the supervision and control of the Collegiate Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued in the school. By the order of the Council, and with the sanction of the Fellows of the College, the School has, during the summer recess of the present year, been enlarged, reconstructed, and fitted with the most approved appliances. The anatomical department has been completely remodelled. The lighting and heating of the dissecting-room have received particular attention. A valuable series of permanent typical dissections have been placed in position round the room, in order that the student may be enabled to study the accurately-displayed parts, and compare his own work therewith. A new laboratory has been constructed for the special accommodation of students in practical physiology. Each student is provided with a microscope, reagents, and all other necessities for making, staining, and mounting microscopic sections. He is, while so engaged, instructed in the minute anatomy of the tissues, and is enabled, during the course, to form and retain for his own use a complete cabinet of about one hundred typical specimens.

THE SCHOOL OF PHYSIC is a medical school formed by an amalgamation of the Schools of Trinity College and of the College of Physicians. The School is governed jointly by the Provost and Senior Fellows of Trinity College, and by the President and Fellows of the College of Physicians, and is situated in the College Park. The Professors in the school are *ex officio* medical officers of Sir Patrick Dun's Hospital. The Arts students of the University have certain advantages in attending at this School, but it is freely accessible to all students, and the instruction provided occupies a high rank.

THE CARMICHAEL COLLEGE OF MEDICINE.—As the buildings are entirely new from their foundation, the directors have been able to provide all the most recent improvements, and to render every department fully adequate to the requirements of the most advanced teaching of medicine and surgery. The School is most conveniently situated, being in immediate proximity to the Meath and Adelaide Hospitals, and it is connected by its teachers not only with these hospitals, but also with the Richmond, Whitworth, and Hardwicke, the Mater Misericordiae, Jervis Street, and the City of Dublin. We would direct attention especially to the dissecting-rooms, and to the physiological laboratory. The former are spacious, well-ventilated, and admirably lighted from the top as well as from the two sides; the latter is completely furnished with every requirement for the practical training of students in physiological and histological research. A bone-room, in which bones, anatomical preparations, &c., are kept, and a student's reading room, have been added this session to the accommodation of the School. Two scholarships, the "Mayne" and the "Carmichael," each value 15*l.*, and prizes to the value of 97*l.*, on the foundation of the late Mr. Carmichael, are offered annually.

THE LEDWICH SCHOOL was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige. Its name was bestowed upon the school as a tribute of respect to the late T. H. Ledwich, who sacrificed a life in an increasing effort to promote its welfare. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, St. Vincent's, Coombe Lying-in Hospital, and Mercer's Hospital, and in the same street with the

Adelaide Hospital and the Carmichael Medical School, and ten minutes' walk from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. Most of its professors are physicians and surgeons of the Mater Misericordiae, St. Vincent's, or Jervis Street Hospitals, and its courses of study qualify for admission to the qualifying examinations of all the licensing bodies. Class prizes are awarded.

CLINICAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—Accommodation: Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds; total, 312 beds. These hospitals are visited each morning at 9 o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Special instruction is also given on various branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There is a very large ophthalmic and aural dispensary, and the respective surgeons give instruction in these important subjects. Eight resident clinical clerks and the dressers are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students as formerly, but also to those who are qualified in medicine or surgery. A house-surgeon for the Richmond Hospital is elected biennially, and receives a salary. The Richmond Lunatic Asylum, containing 1,000 beds, adjoins these hospitals.

CITY OF DUBLIN HOSPITAL is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons and Trinity College. There are special wards for ophthalmic and aural diseases, on which subjects a special course of lectures is delivered. There is a special ward for diseases of women, and a course of lectures given on diseases peculiar to women; there is also a ward exclusively for children. The Drummond Wing is set apart for fever and other contagious diseases. Clinical assistants to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A house-surgeon is elected annually, and medical and surgical pupils are appointed by examination.

THE MEATH HOSPITAL, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 126th year of its existence, ranks among the oldest of the charitable institutions of this city. It is situated on the southern side of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 19th October, 1870; this hospital was, in 1774, constituted the County Dublin Infirmary by Act of Parliament. The present building, in Heytesbury Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. 1853-53 the Collis Wards were added as a memorial to Maurice Collis, twenty-five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Woodhouse.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS are in Peter Street, next door to the Ledwich School and within a few minutes' walk of the Carmichael Medical College, the College of Surgeons, and Trinity College. From the 1st of October the physicians and surgeons will visit the wards, and give instruction at the bedside at the advertised hours. There is a large detached fever hospital and also wards for infants and children. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope. Three resident pupils are selected half-yearly. Prize examinations, including examinations for the Hudson Scholarship, 30*l.*, and a gold medal, and a senior prize of 10*l.*, and a silver medal, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat,

and cutaneous diseases, as well as of minor surgery and dentistry.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It was founded by the School of Physic Act in 1800, and is now governed by the directions laid down in that statute and in the School of Physic Amendment Act, 1867, and it is officered exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was a purely medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now perfectly free to all students.

MATER MISERICORDIÆ HOSPITAL.—This is one of the largest hospitals in Dublin; it contains 280 beds; 50 beds are reserved for fever and other contagious diseases. A special course of lectures on fever will be given during the session. A ward has been assigned for the treatment of ophthalmic diseases, in accordance with the requirements of licensing bodies. The Leonard prizes, value of 30*l.*, will be given at the end of the winter session. The Introductory Lecture will be delivered by Mr. Kennedy on October 30th.

MURKIN'S HOSPITAL, William Street, founded A.D. 1750.—This hospital is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are opened at all hours for the reception of accidents and of acute cases. Dispensaries are held daily and are largely attended. Special instruction is given in cutaneous, infantile, gynecological, and ophthalmic diseases. From the large number of accidents which, from its position, come to the hospital, students are afforded ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms, and of acquiring dexterity in the dressing and manual operations of minor surgery.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The hospital has 160 beds constantly full, and each sister has charge of about twelve patients. In connection with it is the convalescent home at Linden Grove, Blackrock. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. Kehoe, and Dr. Cox. A special ward for the treatment of the diseases of women has been opened under the care of Dr. J. A. Byrne, gynecologist to the hospital. The ophthalmic department is conducted by Mr. D. Redmond. The resident officers consist of a house-surgeon (Mr. Dennis P. Kenna) and two resident pupils. The hospital is visited daily at 9 a.m., and patients are admitted at 10 a.m. Accidents and urgent cases, however, are admitted at all hours. Special arrangements have been made to afford facilities to the students for the study of infectious fevers.

DR. STEEVENS'S HOSPITAL, containing beds for 250 patients is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city otherwise unprovided with medical institutions. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. There is accommodation for residence of two medical and six surgical pupils, besides whom the house surgeon receives house pupils. The fees payable for the privilege of residence are twenty guineas, winter; fifteen guineas, summer six months, which includes the fee for hospital practice for the corresponding terms, and the students in addition to their rooms and furniture are provided with coal and gas. The hospital is easily accessible by two lines of tramway, one of which terminates at the Kingsbridge station within one minute's walk of the hospital.

JARVIS STREET HOSPITAL is one of the oldest-established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character, supplies the hospital with an abundance of surgical cases. Its nursing arrangements are under the charge of a community of Sisters of Mercy. The hospital being found inadequate to the demands upon it, is in process of being rebuilt, and, when finished, will be one of the finest hospitals in Dublin.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda and Coombe Lying-in Hospitals, Cork Street Fever Hospital, Pitt Street Children's Infirmary, St. Mark's Ophthalmic Hospital, the National Eye and Ear Hospital, two Dental Hospitals, the Throat Hospital, and two Orthopedic Hospitals.

THE ROTUNDA HOSPITAL.—This well-known and time-honoured institution possesses a character as a school of midwifery which needs no comment. It is not, however, as generally recognised as it deserves to be as also a great school of gynecology.

COOMBE LYING-IN HOSPITAL.—This hospital, which was rebuilt, considerably enlarged, and re-furnished some years ago, contains 65 beds. It was founded in 1826 by Mrs. Boyle, and was incorporated by Royal Charter in 1867, thus enabling its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It receives about 800 labour cases within its walls, while those attended as extern amount to more than 2,000 in number. Moreover, the chronic hospital for the reception of cases of the diseases of females gives admission to about 200 patients annually. The fee for attendance is 8*l.* 8*s.* for six months as extern, and 18*l.* 18*s.* as internal pupil. During that period the student attends on given days and nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships and a clinical clerkship are obtainable half-yearly by all pupils who have obtained their midwifery diplomas from the hospital, and special certificates are given. Lectures are delivered in the hospital, and clinical instruction is given daily at the bedside. In fact, this hospital is now one of the first clinical hospitals (in this speciality) in Europe.

CORK STREET FEVER HOSPITAL AND HOUSE OF RECOVERY is the only special fever hospital in Dublin. It contains 200 beds, and is supported mainly by an annual Government grant, supplemented by voluntary contributions. A certificate of attendance on fever being now required of candidates for the licence to practise medicine of the King and Queen's College of Physicians in Ireland, arrangements have been made whereby the exceptional advantages connected with this institution can be utilised for purposes of clinical teaching. All particulars may be ascertained on application to Dr. C. Purcell Atkins, Registrar and Resident Medical Officer.

THE PITT STREET CHILDREN'S INFIRMARY, established 1821, was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill are the medical officers.

DUBLIN ORTHOPÆDIC HOSPITAL, 11 Usher's Island, containing 30 beds for the treatment of every class of deformities and the practice of orthopedic surgery. The institution is under the management of Mr. Swan.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL for the treatment of club-foot, contractions and distortions of the limbs, spinal and other bodily deformities, and all non-infectious diseases peculiar to children, 7 Adelaide Road, Dublin. Mr. Ormsby attends on Mondays, Wednesdays, and Fridays; Dr. Woodhouse on Tuesdays, Wednesdays, and Saturdays, from 10 to 11 o'clock, and gives clinical instruction on the intern cases. The hospital is capable of containing 30 beds, for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Fridays. Students and practitioners are allowed to attend the clinical instruction.

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.—This hospital was founded by the late Sir William Wilde. Clinical lectures are delivered on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, at 11 o'clock, and operations are performed on Wednesdays and Saturdays at the same hour. An ophthalmic class meets at 4 p.m. on Mondays, Tuesdays, Wednesdays, and Thursdays.

NATIONAL EYE AND EAR INFIRMARY.—This hospital contains twenty-six beds. Clinical instruction in diseases of the eye, including the use of the ophthalmoscope, is given daily. Operations at twelve o'clock. Instruction in aural surgery is also given. The certificate in clinical ophthalmology from this hospital is recognised by the board of T.C.D., and by the Council of the College of Surgeons in Ireland for the L.R.C.S.I. Students may enter their names for the three months' course any day from 1st October to 1st April.

THE DENTAL HOSPITAL OF IRELAND is open to students, under the following conditions:—Students proposing to attend the practice of the hospital must show certificates of having

attended two full years of surgical study in a recognised school. No student shall be permitted to operate until he has satisfied the professional staff of the hospital of his knowledge of the anatomy of the teeth and jaws. No certificate shall be issued to a student unless he shall have made satisfactory progress during his attendance at the hospital; and it shall be competent for the committee or professional staff to withhold the certificate of any pupil for breach of the bye-laws of the hospital. The fee for attendance at the hospital from 9 till 10.30 a.m. daily for three months has been fixed at £3 3s.

II.—QUALIFICATION.

THE Medical Licensing Bodies of Ireland are five in number, and, as a rule, medical students gravitate into one or other of three classes:—*a.* Those who enter Trinity College, and take a full graduation in Arts, in addition to their professional degrees. *b.* Those who take the Licences of the College of Surgeons with that of the College of Physicians or of the Apothecaries' Hall. *c.* Those who will take their qualifications at the new Royal Irish University, because the graduation in Arts is not necessary in that institution. A fourth minor class is constituted by those who pursue their studies in Ireland, but who, either to escape the extended course of study required in Ireland, or to save the consequent fees, or because they cannot pass the Irish examination, migrate to Edinburgh or Glasgow for their licences. Almost all these emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, almost without exception, in Dublin.

The Irish licensing bodies are as follows:—

THE UNIVERSITY OF DUBLIN grants the degrees of M.B. and B.Ch. to students who have obtained their Arts degree, and the higher degrees of M.D. and M.Ch. to those who have held for at least three years the grade of M.B. and B.Ch. It does not grant degrees to undergraduate students; consequently its licences hold the highest rank as social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degree of Bachelor in Medicine and Bachelor in Surgery in the University of Dublin is approximately as follows:—Lectures, £61 13s.; Hospitals, £44 2s.; Degree Fees, £31 = £136 15s.

The expense of the degree of Bachelor in Arts, amounting altogether to £83 4s., should be added to the foregoing, making the total cost £230.

The University also grants a midwifery degree (M.A.O.) to its own medical graduates, at an additional fee of £5.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.—Candidates must be graduates in Arts, and may obtain the degree at the same commencement as the B.A., or at any subsequent one. The medical education of a Bachelor of Medicine is of four years' duration, and comprises the following lectures:—

Winter Courses.—Anatomy; physiology; practical anatomy; surgery; chemistry; practice of medicine; midwifery; heat, electricity, and magnetism.

Summer Courses.—Botany; materia medica; and pharmacy; practical histology; medical jurisprudence; comparative anatomy. Hospital attendance on a medico-surgical hospital during three courses of nine months each, with clinical lectures, including actual attendance on fever; six months' practical midwifery; six months' dissections; and three months' laboratory instruction in chemistry are required. The Courses may be attended at any recognised medical school. The fee for the *Licent ad Examinandum* is 5l. The fee for the degree of M.B. is 11l.

Doctor in Medicine.—A Doctor in Medicine must be M.B., or qualified to take that degree for three years. He must also read a thesis before the Regius Professor of Physic. Total fee for this degree, 13l.

Bachelor in Surgery must be B.A., have spent four years in the study of surgery and anatomy, and passed the M.B. examination. The curriculum comprises the following, in addition to the course for the M.B.:—Theoretical and operative surgery, one course; Dissection, two courses; Ophthalmic surgery, one course. Candidates are required to perform operations on the dead subject. Fee for the *Licent ad Examinandum*, £5. Fee for the degree of Bachelor in Surgery, £5.

Master in Surgery must be a B.Ch. of three years' standing, and must read a thesis. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations, and produce certificates of having completed the following curriculum:—1. One Winter Course in midwifery. 2. Six months' practice in a recognised lying-in hospital or maternity. 3. A Summer Course in obstetric medicine and surgery. 4. Two months' practice in the Cow-pock Institution, or in the Grand Canal Street Dispensary. Graduates of Medicine of M.D. standing may present themselves for examination without complying with Regulations 3 and 4. Fee for the degree of M.A.O., £5.

Candidates for the licence in medicine or surgery must be matriculated in medicine, and must have completed two years in Arts.

Licentiate in Medicine.—The course and examination are the same as for the M.B. An L.M. on proceeding to the degree of B.A. may become an M.B. on paying the fees without further examination. Fee for the *Licent ad Examinandum*, £5. Fee for the licence in medicine, £5.

Licentiate in Surgery.—The course and examination necessary for the licence in surgery is the same as for the degree of Bachelor in Surgery. Fee for the *Licent ad Examinandum* £5. For the licence in surgery, £5.

ROYAL UNIVERSITY OF IRELAND.—The University confers the following medical degrees:—

Bachelor of Medicine, M.B.; Doctor of Medicine, M.D., Master of Surgery, M.Ch.; in Obstetrics, a special diploma; in Sanitary Science, a special diploma.

All degrees are open to persons of either sex. The examinations for women are held apart from those for men, but upon the same days.

The University examinations commence on the third Tuesday in September.

Candidates for any degree must have passed the Matriculation Examination of the University. *Students from other Universities are included.*

This examination shall be conducted not only in Dublin, but at certain local centres selected by the Senate.

Every candidate must send in to the secretaries his name and address, and pay a fee of 10s.

The following are subjects:—

I. Latin. II. Any one of the following languages:—Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic. III. English language. IV. Elementary Mathematics. V. Experimental Physics.

Candidates for all degrees must pass the First University Examination.

The courses for the degrees of M.B. and M.Ch., and the Diplomas in Obstetrics and in Sanitary Science, extend over at least four years. Candidates will be required, in addition to the First University Examination, to pass the following Examinations:—

- First Professional Examination.
- Second Professional Examination.
- The Degree Examination.

They may, however, pass the First University Examination at the same time as the First Professional Examination.

Candidates for the M.D. may present themselves after the lapse of two Academical years from the date of obtaining the degree of M.B. Those candidates who are Students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the Degree Examination.
